

***Comprehensive assessment of the potential for efficiency in heating and cooling in Croatia under Annex VIII to Directive 2012/27/EU***

**Commissioned by:**

Ministry of the Economy and Sustainable  
Development

**Address of the Client:**

Radnička cesta 80, 10000 ZAGREB

**Contact person of the Client:**

Boris Makšijan

***Comprehensive assessment of the potential for  
efficiency in heating and cooling in Croatia under  
Annex VIII to Directive 2012/27/EU***

**Authors of the Study:**

Ivan Bačan

Toni Borković

Ružica Budim

Vesna Bukarica

Dinko Đurđević

Alenka Kinderman Lončarević

Anita Knezović

Vedran Krstulović

Marina Malinovec Puček

Jadranka Maras

Igor Novko

Dražen Tumara

Branko Vuk

Sanja Živković

**Study development coordinator:**

Marina Malinovec Puček

**Code of the Study:**

STU-21-00001/1

Energy Institute Hrvoje Požar, Savska cesta 163, Zagreb

## TABLE OF CONTENTS

<b>TABLE OF CONTENTS</b>	<b>I</b>
<b>LIST OF ABBREVIATIONS</b>	<b>1</b>
<b>LIST OF TABLES</b>	<b>2</b>
<b>LIST OF FIGURES</b>	<b>9</b>
<b>EXECUTIVE SUMMARY</b>	<b>14</b>
<b>METHODOLOGICAL APPROACH AND INPUT DATA USED IN PREPARING THE COMPREHENSIVE ANALYSIS</b>	<b>17</b>
<b>DIO I. OVERVIEW OF HEATING AND COOLING</b>	<b>27</b>
<b>1 ANNUAL USEFUL ENERGY DELIVERED AND REQUIRED FOR HEATING/COOLING BY SECTOR</b>	<b>28</b>
1.1 Croatia's energy balance in 2019	28
1.2 Annual energy delivered for heating/cooling by sector	36
1.3 Annual useful energy needs for heating/cooling by sector	95
<b>2 ANNUAL ENERGY DELIVERED FOR HEATING/COOLING PURPOSES BY SECTOR AND TECHNOLOGY</b>	<b>119</b>
2.1 Annual energy delivered for heating/cooling purposes by sector and technology	119
2.2 Identification of the installations generating waste heat or cold and their potential for heating or cooling supply	126
2.3 Sources of geothermal energy – existing and potential	134
2.4 Reported share of energy from renewable sources and waste heat or cold in the consumption of delivered energy in the sector of district heating systems in the past 5 years under Directive (EU) 2018/2001	142
<b>3 MAPS OF CROATIA</b>	<b>144</b>
3.1 Map of Croatia – annual delivered and required useful energy for heating/cooling	144
3.2 Map of Croatia – district heating systems	149
3.3 Map of Croatia – supply points of industrial facilities generating waste heat	154
3.4 Map of Croatia – geothermal springs	156
<b>4 FORECAST OF DEVELOPMENTS IN ANNUAL USEFUL [ENERGY] DELIVERED AND NEEDED FOR HEATING/COOLING IN THE NEXT 10 AND 30 YEARS</b>	<b>158</b>

---

4.1	Projections of demographic trends	158
4.2	Projections of trends in the national building stock	159
4.3	Projections of developments in useful energy delivered and needed for heating/cooling	163
<b>DIO II. OBJECTIVES, STRATEGIES AND POLICY MEASURES</b>		
<b>171</b>		
<b>5 CROATIA'S PLANNED CONTRIBUTION WITH ITS NATIONAL OBJECTIVES, TARGETS AND CONTRIBUTIONS TO THE FIVE DIMENSIONS OF THE ENERGY UNION</b>		
<b>172</b>		
5.1	Decarbonisation	172
5.2	Energy efficiency	173
5.3	Energy security	174
5.4	Internal energy market	175
5.5	Research, innovation and competitiveness	175
<b>6</b>	<b>GENERAL OVERVIEW OF EXISTING POLICIES AND MEASURES</b>	<b>176</b>
<b>DIO III. ANALYSIS OF THE ECONOMIC POTENTIAL FOR EFFICIENT HEATING AND COOLING</b>		
<b>178</b>		
<b>7 ANALYSIS OF THE ECONOMIC POTENTIAL OF DIFFERENT HEATING AND COOLING TECHNOLOGIES</b>		
<b>179</b>		
7.1	Calculation of average and maximum heating and cooling load	179
7.2	Defining technical criteria necessary for heat network connection	181
7.3	Determining the technical potential	181
<b>8</b>	<b>COST-BENEFIT ANALYSIS</b>	<b>207</b>
8.2	Sensitivity analysis	231
8.3	DISCUSSION AND CONCLUSION	234
<b>DIO IV. POTENTIAL NEW STRATEGIES AND POLICY MEASURES</b>		
<b>241</b>		
<b>9 OVERVIEW OF NEW LEGISLATIVE AND NON-LEGISLATIVE POLICY MEASURES</b>		
<b>242</b>		
<b>MISCELLANEOUS</b>		
<b>251</b>		
<b>ANNEXES</b>		
<b>252</b>		
<b>REFERENCES</b>		
<b>312</b>

## LIST OF ABBREVIATIONS

BAU	reference or baseline scenario (business-as-usual)
CBA	cost-benefit analysis
WMC	waste management centre
DHS	district heating system
CBS	Croatian Bureau of Statistics
DHC	district heating and cooling
EIHP	Energy Institute Hrvoje Požar
ESCO	energy service company
ESI	European Structural and Investment Funds
RDF	refuse-derived fuel
CAEN	Croatian Agency for the Environment and Nature
HEP ODS	<i>Hrvatska Elektroprivreda – Operator Distribucijskog Sustava</i> [state-owned power company – distribution system operator]
HERA	Croatian Energy Regulatory Agency
HROTE	Croatian Energy Market Operator
IEA	International Energy Agency
IEC	Energy Certification Information System
JRC	Joint Research Centre
MBT	mechanical biological waste treatment
MESD	Ministry of the Economy and Sustainable Development
NECP	National Energy and Climate Plan
NAC	National Classification of Activities
NRRP	National Recovery and Resilience Plan
NPV	net present value
RES	renewable energy source
DHW	domestic hot water
SPF	seasonal performance factor of a heat pump
LPG	liquefied petroleum gas
CHS	closed heating system
SIM	scenario with integrated measures
HEC	high-efficiency cogeneration
CWMC	County Waste Management Centre

---

## LIST OF TABLES

Table 0.1: Croatia's projected population size for 2019 by county .....	21
Table 0.2: National building stock by county .....	22
Table 0.3: Residential building stock by county .....	23
Table 0.4: Non-residential building stock by county.....	25
Table I.1: Final energy consumption in Croatia, 2019.....	29
Table I.2: Final energy consumption in Croatia, 2019.....	30
Table I.3: HOUSEHOLD SECTOR – Distribution of total final energy consumption by energy product according to the Eurostat method, 2019 .....	31
Table I.4: SERVICE SECTOR – Distribution of the total final energy consumption by energy product according to the Eurostat method, 2019 .....	32
Table I.5: INDUSTRIAL SECTOR – Distribution of the total final energy consumption by energy product according to the Eurostat method, 2019 .....	34
Table I.6: Total annual energy delivered for heating/cooling in Croatia by sector, 2019.....	36
Table I.7: HOUSEHOLD SECTOR – Distribution of total energy delivered (without renewable energy for space heating taken from the environment using heat pumps).....	38
Table I.8: HOUSEHOLD SECTOR – Distribution of the total energy delivered for space heating/cooling and DHW preparation by building type .....	38
Table I.9: HOUSEHOLD SECTOR – Distribution of the electricity consumption for space heating .....	39
Table I.10: HOUSEHOLD SECTOR – Distribution of the electricity consumption for space heating .....	40
Table I.11: HOUSEHOLD SECTOR – Distribution of the total energy delivered (with renewable energy for space heating taken from the environment using heat pumps) .....	40
Table I.12: HOUSEHOLD SECTOR – Distribution of the total energy delivered for space heating/cooling and DHW preparation (with renewable energy for space heating taken from the environment using heat pumps) .....	41
Table I.13: HOUSEHOLD SECTOR – Distribution of total energy delivered by purpose (with renewable energy taken from the environment using heat pumps for space heating) .....	42
Table I.14: HOUSEHOLD SECTOR – Distribution of total energy delivered for space heating by type of space heating system technology (with renewable energy taken from the environment using heat pumps for space heating).....	43
Table I.15: HOUSEHOLD SECTOR – Distribution of total energy delivered for space cooling by type of space cooling system technology.....	43
Table I.16: HOUSEHOLD SECTOR – Distribution of total energy delivered for DHW preparation by DHW system technology.....	45
Table I.17: HOUSEHOLD SECTOR – Ranking of counties (top six) by consumption of total annual energy delivered for space heating/cooling and DHW preparation (with renewable energy taken from the environment using heat pumps for space heating) .....	46
Table I.18: HOUSEHOLD SECTOR – Distribution of total energy delivered for space heating/cooling and DHW preparation by county and energy product (with renewable energy taken from the environment using heat pumps for space heating) .....	48

---

Table I.19: HOUSEHOLD SECTOR – Distribution of total energy delivered for space heating by building type and county (with renewable energy taken from the environment using heat pumps for space heating) .....	49
Table I.20: HOUSEHOLD SECTOR – Distribution of total electricity delivered for space cooling by building type and county.....	50
Table I.21: HOUSEHOLD SECTOR – Distribution of total energy delivered for DHW preparation by building type and county.....	50
Table I.22: HOUSEHOLD SECTOR – Distribution of total energy delivered for space heating by building type and energy product (with renewable energy taken from the environment using heat pumps for space heating) .....	51
Table I.23: HOUSEHOLD SECTOR – Distribution of total energy delivered for DHW preparation by building type and energy product.....	52
Table I.24: SERVICE SECTOR – Energy delivered for heating, DHW preparation and cooling by energy product.....	54
Table I.25: SERVICE SECTOR – Energy delivered for heating, DHW preparation and cooling by building type at county level .....	56
Table I.26: SERVICE SECTOR – Energy delivered for heating, DHW preparation and cooling by energy product at county level .....	57
Table I.27: Overview of the main sections of activities with divisions.....	58
Table I.28: Overview of industrial sector divisions.....	59
Table I.29: INDUSTRIAL SECTOR – List of energy products taken into account .....	60
Table I.30: INDUSTRIAL SECTOR – Use of electricity and natural gas as energy product for covering heating/cooling needs.....	61
Table I.31: INDUSTRIAL SECTOR – Total energy delivered from the energy products taken into account .....	64
Table I.32: INDUSTRIAL SECTOR – Total annual energy delivered for heating/cooling by county and energy product.....	68
Table I.33: INDUSTRIAL SECTOR – Total annual energy delivered for heating/cooling by purpose and energy product.....	68
Table I.34: Distribution of total electricity delivered according to needs, using manufacture of mill products and beer as examples .....	69
Table I.35: INDUSTRIAL SECTOR – Distribution of electricity delivered by counties .....	70
Table I.36: INDUSTRIAL SECTOR – Distribution of network-distributed natural gas delivered by counties .....	70
Table I.37: INDUSTRIAL SECTOR – Distribution of energy delivered from steam and water at temperatures lower than or equal to 200 °C by counties.....	71
Table I.38: INDUSTRIAL SECTOR – Distribution of energy delivered from steam and water at temperatures higher than 200 °C by counties .....	71
Table I.39: INDUSTRIAL SECTOR – Distribution of a portion of the total electricity delivered for space heating/cooling of offices and DHW preparation .....	72
Table I.40: INDUSTRIAL SECTOR – Distribution of electricity delivered by counties .....	73
Table I.41: INDUSTRIAL SECTOR – Total annual energy delivered for heating/cooling by county .....	75

Table I.42: INDUSTRIAL SECTOR - Total energy delivered for heating/cooling.....	75
Table I.43: INDUSTRIAL SECTOR – Total energy delivered by type of activity .....	79
Table I.44: INDUSTRIAL SECTOR – Industrial boiler rooms – Total annual consumption of energy sources for steam and water generation, 2019 .....	80
Table I.45: INDUSTRIAL SECTOR – Industrial boiler rooms – Total annual consumption of energy products to generate steam and water at temperatures lower than or equal to 200 °C, 2019.....	82
Table I.46: INDUSTRIAL SECTOR – Industrial boiler rooms – Total annual consumption of energy sources to generate steam and water temperature higher than 200 °C, 2019 .....	83
Table I.47: INDUSTRIAL SECTOR – Industrial boiler rooms – Total annual consumption of energy sources for steam and water generation, 2019 .....	84
Table I.48: INDUSTRIAL SECTOR – Industrial boiler rooms – Total annual consumption of energy sources for steam generation from fossil fuels and RES, 2019 .....	85
Table I.49: INDUSTRIAL SECTOR – Industrial cogeneration installations – Total annual consumption of drive energy products for electricity and thermal energy generation, 2019.....	86
Table I.50: INDUSTRIAL SECTOR – Overview of industrial cogeneration installations (2019) .....	88
Table I.51: INDUSTRIAL SECTOR – DHS – Distribution of DHS thermal energy delivered by generation technology.....	90
Table I.52: Overview of the energy delivered for heating/cooling purposes to the industrial sector in 2019, according to the template prepared by the European Commission.....	92
Table I.53: INDUSTRIAL SECTOR – Distribution of total annual energy delivered for heating/cooling by purpose.....	93
Table I.54: Overview of energy delivered and useful energy needed by sectors in 2019, according to the template prepared by the European Commission.....	95
Table I.55: Total annual energy delivered and useful energy needed for heating/cooling in Croatia by sector, 2019.....	96
Table I.56: Total annual energy delivered and useful energy needed for heating in Croatia by sector, 2019.....	97
Table I.57; Total annual energy delivered and useful energy needed for cooling in Croatia by sector, 2019.....	98
Table I.58: HOUSEHOLD SECTOR – Degree of efficiency, i.e. coefficient of performance for heating and cooling factor.....	100
Table I.59. HOUSEHOLD SECTOR – Overview of the annual energy delivered and useful energy needed for heating/cooling.....	101
Table I.60. HOUSEHOLD SECTOR – Total annual useful energy needs.....	102
Table I.61: HOUSEHOLD SECTOR – Distribution of total useful energy needed for space heating/cooling and DHW preparation by county .....	104
Table I.62: HOUSEHOLD SECTOR – Ranking of counties (top six) by total annual useful energy needed for space heating/cooling and DHW preparation .....	104
Table I.63: HOUSEHOLD SECTOR – Family houses – Trends in specific useful energy needed for space heating by county.....	109
Table I.64: HOUSEHOLD SECTOR – Multi-apartment buildings – Trends in specific useful energy needed for space heating by county .....	110

Table I.65: HOUSEHOLD SECTOR – Trends in specific useful energy needed for space heating .....	110
Table I.66: HOUSEHOLD SECTOR – Trends in specific useful energy needed for DHW preparation ..	111
Table I.67: HOUSEHOLD SECTOR – Trends in specific useful energy needed for space cooling.....	111
Table I.68: SERVICE SECTOR – Energy needed for heating, DHW preparation and cooling by building type.....	112
Table I.69: SERVICE SECTOR – Overview of the annual energy delivered and useful energy needed for heating/cooling .....	113
Table I.70: SERVICE SECTOR – Energy needed for heating, DHW preparation and cooling by building type at county level .....	115
Table I.71: SERVICE SECTOR – Overview of the annual useful energy delivered and needed for heating/cooling by purpose .....	116
Table I.72: INDUSTRIAL SECTOR – Overview of the annual energy delivered and useful energy needed for heating/cooling.....	117
Table I.73: Total annual energy delivered for heating/cooling purposes in Croatia by sector, 2019 .	121
Table I.74: Overview of the energy delivered for heating/cooling by sector in 2019, according to the template prepared by the European Commission .....	123
Table I.75: Total annual energy delivered for heating/cooling purposes in Croatia by sector, 2019 .	124
Table I.76: Total annual energy delivered for heating/cooling by sector and purpose in Croatia, 2019 .....	124
Table I.77: Results of the high-efficiency cogeneration analysis at HEP Proizvodnja d.o.o. production plants.....	129
Table I.78: Potential of waste heat recovery in various industries .....	132
Table I.79: Annual available waste heat and power from the industrial sector at county level .....	134
Table I.80: Geothermal energy use in Croatia.....	134
Table I.81: Potential sources of geothermal energy .....	140
Table I.82: District heating systems in Croatia – origin of produced thermal energy delivered to household and service sectors .....	142
Table I.83: Share of RES in the district heating sector, 2015–2019 .....	142
<i>Table I.84: Shares of RES in the district heating sector – 2019 data.....</i>	<i>143</i>
Table I.85: Overview of the formats of provided infrastructure data on district heating systems ....	150
Table I.86: Projection of Croatia’s population size until 2030 by county – Variant 2 .....	158
Table I.87: Projection of trends in Croatia’s residential building stock by county until 2050 .....	161
Table I.88: Projection of trends in Croatia’s non-residential building stock by county until 2050 .....	162
Table I.89: BAU scenario – projections of developments in total annual delivered energy by sector, 2019–2050.....	163
Table I.90: BAU scenario – projections of developments in total annual energy delivered by purpose for 2019–2050 .....	164
Table I.91: BAU scenario – projections of developments in total annual energy delivered to household and service sectors by purpose and energy product .....	164

Table I.92: BAU scenario – projections of developments in total annual useful energy by sector for 2019–2050.....	165
Table I.93: BAU scenario – projections of developments in total annual useful energy by purpose for 2019–2050.....	166
Table I.94: Scenario with integrated measures – projections of developments in the total annual energy delivered by sector, 2019–2030.....	167
Table I.95: Scenario with integrated measures – projections of developments in the total annual energy delivered by purpose, 2019–2050.....	167
Table I.96: Scenario with integrated measures – projections of developments in the total annual energy delivered to household and service sectors by purpose and energy product.....	168
Table I.97: Scenario with integrated measures – projections of developments in total annual useful energy by sector for 2019–2050 .....	169
Table I.98: Scenario with integrated measures – projections of developments in total annual useful energy by purpose for 2019–2050 .....	170
Table II.1. Estimated contribution of RES technologies in heating and cooling (Source: NECP).....	173
Table III.1: Average and maximum heating/cooling load for heating/cooling by sector:.....	180
Table III.2: Maximum heating load for heating by sector and by county .....	180
Table III.3: Maximum cooling load for cooling by sector and by county .....	180
Table III.4: DHS – total annual energy delivered at the entry point to the distribution network of district heating systems in 2019, 2030 and 2050.....	183
Table III.5. DHS – Installed capacity needed and annual primary energy and CO <sub>2</sub> emissions savings after the implementation of the proposed measures .....	187
Table III.6: Basic information on the KKE EL-TO Zagreb project.....	189
Table III.7: Basic information on the KKE Osijek 500 project .....	189
Table III.8: Representation of the status of waste management centres in Croatia (source: EIHP)...	195
Table III.9: Potential of the utilised energy from thermal waste treatment.....	198
Table III.10: HOUSEHOLD SECTOR – Installed capacity needed and annual primary energy and CO <sub>2</sub> emissions savings after the implementation of measures for efficient space heating.....	201
Table III.11: HOUSEHOLD SECTOR – Installed capacity needed and annual primary energy and CO <sub>2</sub> emissions savings after the implementation of measures for DHW preparation .....	202
Table III.12: HOUSEHOLD SECTOR – Installed capacity needed and annual primary energy and CO <sub>2</sub> emissions savings after the implementation of measures for efficient space cooling .....	203
Table III.13: HOUSEHOLD SECTOR – Percentage of energy product increase/decrease under the BAU scenario after the implementation of measures for efficient heating, DHW preparation and cooling .....	203
Table III.14: SERVICE SECTOR – Installed capacity needed and annual primary energy and CO <sub>2</sub> emissions savings resulting from the implementation of measures for efficient space heating .....	204
Table III.15: SERVICE SECTOR – Installed capacity needed and annual primary energy and CO <sub>2</sub> emissions savings resulting from the implementation of measures for efficient DHW preparation.....	205
Table III.16: SERVICE SECTOR – Installed capacity needed and annual primary energy and CO <sub>2</sub> emissions savings resulting from the implementation of measures for efficient space cooling.....	205

Table III.17: SERVICE SECTOR – Percentage of energy product increase/decrease under the BAU scenario after the implementation of measures for efficient heating, DHW preparation and cooling .....	206
Table III.18: Energy products and technologies in the BAU scenario .....	208
Table III.19: Overview of energy products and technologies in alternative scenarios .....	208

## EXECUTIVE SUMMARY

Heating and cooling systems are the most important final energy consumers with an energy consumption of about 50% of total energy requirements in the European Union. Buildings account for 80% of the energy consumed. To ensure the energy transition at every administrative level within the EU, it is necessary to:

- identify energy efficiency potential to achieve savings across all Member States; and;
- align policies.

Under Article 14 of **Directive 2012/27/EU** of the European Parliament and of the Council of 25 October 2012 **on energy efficiency** (EED), as of 31 December 2015, Member States are required to carry out a **comprehensive assessment of the potential for the application of high-efficiency cogeneration and efficient district heating and cooling** (hereinafter: comprehensive assessment) and notify it to the Commission.

As part of the comprehensive assessment, Member States adopt policies which encourage due taking account of the possibilities of using efficient heating and cooling systems, particularly high-efficiency cogeneration systems, at local and regional levels, also taking into account the potential for local and regional heat market development.

The comprehensive assessment is updated at the request of the Commission and notified to the Commission every 5 years.

Croatia's first comprehensive assessment, entitled *Programme of Exploiting Heating and Cooling Efficiency Potential for 2016–2030*, was prepared in November 2015.

This Comprehensive Assessment is structured in line with Annex VIII to the Commission Delegated Regulation (EU) 2019/826 of 4 March 2019 amending Annexes VIII and IX to Directive 2012/27/EU of the European Parliament and of the Council on the contents of comprehensive assessments of the potential for efficient heating and cooling [5]:

PART I: OVERVIEW OF HEATING AND COOLING

PART II: OBJECTIVES, STRATEGIES AND POLICY MEASURES

PART III: ANALYSIS OF THE ECONOMIC POTENTIAL FOR EFFICIENT HEATING AND COOLING

PART IV: POTENTIAL NEW STRATEGIES AND POLICY MEASURES

Part I of the Comprehensive Assessment provides an overview of delivered and useful heating/cooling energy, broken down by main sectors (households, services, industry) at the level of municipalities, towns and cities, and City of Zagreb districts in 2019. The delivered and useful heating/cooling energy is then shown at those levels on a map of Croatia. Maps also show the existing district heating systems in Croatia (generation facilities and distribution network), points of supply of the industrial facilities generating waste heat, and existing and potential sources of geothermal energy. At the end of Part I, forecast trends in the annual useful [energy] for heating/cooling delivered and required are provided for the baseline scenario and a scenario with integrated measures for the period up to 2050. In 2019, total annual energy delivered for heating/cooling purposes to household, service and industrial sectors in Croatia amounted to 33 505.18 GWh, while the annual useful energy needed for heating/cooling in those sectors totalled 32 366.55 GWh. The share of energy from renewable sources in district heating systems was declared at 4.9% in 2019.

Part II specifies the existing objectives, strategies and policy measures, that is, Croatia's planned contribution with its national objectives, targets and contributions to the five closely-related dimensions of the Energy union: energy security, internal energy market, energy efficiency,

decarbonisation, as well as research, innovation and competitiveness. Croatia has already adopted its national objectives and targets relating to the five dimensions of the Energy union in the Integrated National Energy and Climate Plan (NECP) for 2021–2030. With regard to heating and cooling, it is crucial to note that the target share of renewable energy sources (RES) in gross final energy consumption for heating and cooling has been set at 47.8% for 2030, compared to a 36.8% share in 2020. Improved efficiency and decarbonisation of heating and cooling systems are integral elements of the building renovation programme, as the most relevant measures for achieving both RES-related objectives and energy efficiency targets. The NECP also envisages ways to stimulate biomethane and hydrogen production with the aim of decarbonising the gas system, as well as further upgrading and development of district heating systems by enhancing the efficiency of generation facilities, integrating RES and reducing losses in the existing distribution network.

Part III of the Comprehensive Assessment, relating to the analysis of the economic potential for efficient heating and cooling, lays down the technical and economic potential and includes a cost-benefit analysis, conducted to identify the most cost-efficient solutions for meeting heating and cooling requirements in the three Croatian sectors observed. A sensitivity analysis, undertaken to determine how a variation of individual parameters or a combination of parameters affects final results of the calculation (economic potential and the most cost-effective solutions for meeting heating and cooling requirements), is included at the end of Part III. Alternative or SIM scenarios developed as part of the analysis of the economic potential for efficient heating and cooling were compared to baseline and BAU scenarios. Results show that proposed alternative scenarios lead to lower CO<sub>2</sub> emissions and lower costs than BAU scenarios. Total CO<sub>2</sub> emissions savings achieved by implementing the proposed measures for both periods observed (up to 2030 and 2031–2050) are as follows:

HOUSEHOLDS – individual systems → 1 160 975.65 tonnes of CO<sub>2</sub>;

SERVICES – individual systems → 818 845.07 tonnes of CO<sub>2</sub>;

HOUSEHOLDS – SERVICES – INDUSTRY – centralised systems or → DHS 365 013.51 tonnes of CO<sub>2</sub>.

The cost-benefit analysis, performed separately for each measure and for each period in question (up to 2030 and 2031–2050), based on the calculation of the financial net present value (FNPV) and the economic NPV (ENPV), determined the cost-effectiveness of each proposed measure for individual systems in household and service sectors, as well as for district heating systems in the household, services and industrial sectors.

Given that the measures were observed over two periods (a shorter period up to 2030 and a longer one, between 2031 and 2050), some measures turned out not to be cost-effective (FNPV < 0 and ENPV < 0) due to the shorter observation period (measures up to 2030), whereas in the longer observation period the same measures (2031–2050 measures) proved cost-effective when supported (FNPV < 0 and ENPV > 0) or even without the necessary support (FNPV > 0 and ENPV > 0).

The replacement of traditional biomass in the case of individual systems in the household sector proved not to be cost-effective, whereas replacing fuel oil-fired boilers and LPG with all proposed technologies was cost-effective. Replacing natural gas with other technologies is generally cost-effective without necessary support, but some of the proposed technologies for the replacement of natural gas-fired boilers do require public support (installation of solar collectors for DHW preparation, replacement of natural gas boilers with modern biomass-fired boilers for space heating and DHW preparation). When it comes to individual systems in the service sector, the replacement of fuel oil and LPG-fired boilers with all the proposed technologies is a cost-effective measure. As in the household sector, replacing natural gas with other technologies is generally cost-effective without the necessary support; however, some of the proposed technologies for replacing natural gas boilers (installation of solar collectors for DHW preparation in service sector buildings where technically feasible and justified, replacement of natural gas boilers with modern biomass boilers for space heating and DHW preparation) do require public support.

DHS measures which are extremely important and cost-effective when supported relate to the exploitation of geothermal energy and utilisation of industrial waste heat. In addition, the sensitivity analysis showed which of the parameters can have a more significant impact on the outcome of a particular measure.

The final part, Part IV, provides the following potential new strategies and strategic policy measures, which would realise the economic potential for efficiency in heating and cooling, identified in the previous part of the Comprehensive Assessment (PART III):

- INDIVIDUAL SYSTEMS<sup>1</sup> – HOUSEHOLD SECTOR:
  - replacement of natural gas boilers with combined heat and power (micro-CHP) system, fuelled by natural gas (between 2030 and 2050);
  - installation of solar collectors for DHW preparation where natural gas central boilers are used for DHW preparation;
  - replacement of natural gas boilers with modern biomass boilers for space heating and DHW preparation, and installation of solar collectors for DHW preparation;
  - replacement of individual electric space heaters with heat pumps (by 2030);
- INDIVIDUAL SYSTEMS – SERVICE SECTOR:
  - installation of solar collectors for DHW preparation where natural gas central boilers are used for DHW preparation;
  - replacement of natural gas boilers with modern biomass boilers for space heating and DHW preparation, and installation of solar collectors for DHW preparation (where technically feasible and justified in service sector buildings);
- DISTRICT HEATING SYSTEMS<sup>2</sup> – increased efficiency and expansion of the distribution network of existing district heating systems in densely populated urban areas;
- DISTRICT HEATING SYSTEMS – modernisation of generation facilities of existing district heating systems:
  - replacement of natural gas boilers – industrial waste heat utilisation;
  - replacement of natural gas boilers – geothermal energy exploitation.

The comprehensive assessment of the potential for efficient heating and cooling in Croatia under Annex VIII to Directive 2012/27/EU shows notably the existence of great potential for an efficient district heating system in Croatia, based on the use of renewable energy sources (primarily geothermal energy) and high-efficiency cogeneration from natural gas and biomass, as well as considerable potential through the application of measures relating to individual systems in household and service sectors.

---

<sup>1</sup> Each consumer has their own separate source of heating and/or cooling energy.

<sup>2</sup> District heating systems used for heat distribution from the source (generation installation) to consumers.

## METHODOLOGICAL APPROACH AND INPUT DATA USED IN PREPARING THE COMPREHENSIVE ANALYSIS

### a) Methodological approach

The first set of comprehensive assessments was analysed by the **Joint Research Centre (JRC)**, which found that they could benefit from the collected new data, descriptions of new heating and cooling potentials, and a better interaction between national and local administrations.

In a letter of 8 April 2019, the European Commission asked all Member States to submit their most recent, updated comprehensive assessments of the potential for efficient heating and cooling by 31 December 2020 at the latest.

As part of the second comprehensive assessment, it is necessary to, among other things, ensure better alignment with the following Energy union regulations:

- **Regulation (EU) No 2018/1999** of the European Parliament and of the Council of 11 December 2018 **on the Governance of the Energy Union and Climate Action**,
- **Directive (EU) 2018/844** of the European Parliament and of the Council of 30 May 2018 **amending Directive 2010/31/EU on the energy performance of buildings and Directive 2012/27/EU on energy efficiency**,
- **Directive (EU) 2018/2002** of the European Parliament and of the Council of 11 December 2018 **amending Directive 2012/27/EU on energy efficiency**,
- **Directive (EU) 2018/2001** of the European Parliament and of the Council of 11 December 2018 **on the promotion of the use of energy from renewable sources**.

The preparation of the analyses should be closely related to the planning and reporting set out in Regulation (EU) 2018/1999 on the Governance of the Energy Union and Climate Action, as well as based on previous assessments wherever possible.

The content of the comprehensive assessment is laid down in **Annex VIII** to Directive 2012/27/EU. Annexes VIII and IX to Directive 2012/27/EU were amended by Commission Delegated Regulation (EU) 2019/826 of 4 March 2019. With regard to the content of the comprehensive assessment, it is important to take note of the following Commission Recommendation and its Annexes:

- Commission Recommendation of 25 September 2019 on the content of the comprehensive assessment of the potential for efficient heating and cooling under Article 14 of Directive 2012/27/EU,
- Annexes to Commission Recommendation of 25 September 2019 on the content of the comprehensive assessment of the potential for efficient heating and cooling under Article 14 of Directive 2012/27/EU.

Commission Recommendation of 25 September 2019 contains the following Annexes:

Annex I: Contents of comprehensive assessments of the potential for efficient heating and cooling

Annex II: Additional sources of literature

Annex III: Waste heat accounting

Annex IV: Process for comprehensive assessments (Annex VIII EED)

Annex V: Financial and economic cost-benefit analysis

Annex VI: External costs of the cost-benefit analysis

## Annex VII: Reporting template for reporting inputs and outputs

which explain the new requirements and facilitate the effective and coherent application of the provisions of Annex VIII EED.

Definitions of particular terms defined by Directive 2012/27/EU, which are relevant for this comprehensive assessment, are as follows:

- **high-efficiency cogeneration** – cogeneration meeting the criteria laid down in Annex II (Methodology for determining cogeneration process efficiency);
- **efficient district heating and cooling** – a district heating or cooling system using at least 50% renewable energy, 50% waste heat, 75% cogenerated heat or 50% of a combination of such energy and heat;
- **efficient heating and cooling** – a heating and cooling option that, compared to a baseline scenario reflecting a business-as-usual situation, measurably reduces the input of primary energy needed to supply one unit of delivered energy within a relevant system boundary in a cost-effective way, as assessed in the cost-benefit analysis referred to in this Directive, taking into account the energy required for extraction, conversion, transport and distribution;
- **efficient individual heating and cooling** – an individual heating and cooling supply option that, compared to efficient district heating and cooling, measurably reduces the input of non-renewable primary energy needed to supply one unit of delivered energy within a relevant system boundary or requires the same input of non-renewable primary energy but at a lower cost, taking into account the energy required for extraction, conversion, transport and distribution.

The comprehensive assessment included a cost-benefit analysis, which identified the most cost-efficient solutions for meeting heating and cooling needs.

As a first step, the total annual energy delivered for heating/cooling purposes was defined, and the useful energy required for heating and cooling was determined for the following main sectors:

- household sector (residential sector),
- service sector,
- industry,
- agriculture,

and for the relevant sub-sectors:

- **household sector:**
  - family houses,
  - multi-apartment buildings,
- **service sector:**
  - public buildings,
  - educational buildings (kindergartens, primary schools, secondary schools, universities),
  - hotels,
  - hospitals,
  - shops,
  - office buildings,

- other,
- **industry:**
  - breakdown by key activity, e.g. cement industry, cellulose and paper, metallurgy,

Given that data on service sector buildings (useful floor area of the heated part of the building  $A_k$ , energy products used for space heating and cooling or DHW preparation) was taken from the Energy Certification Information System (Cr. abbr. IEC) database, the rest of the study makes use of the following sub-sectors of the service sector, in accordance with the breakdown specified in the *Rules governing energy audits and energy performance certification of buildings (Narodne Novine (NN; Official Gazette of the Republic of Croatia) No 88/2017)*:

- office buildings,
- educational buildings (kindergartens, primary schools, secondary schools, universities),
- hospitals,
- hotels and restaurants,
- sports halls,
- wholesale and retail trade buildings,
- other non-residential buildings heated to a temperature of +18 °C (e.g. traffic and communication buildings, terminals, stations, post offices, telecommunications buildings, buildings for artistic and cultural activities and entertainment, museums, libraries).

After determining the currently required useful energy for heating and cooling, the annual useful energy required for heating and cooling was estimated. Defining the current and future useful energy requirements for heating/cooling is extremely important because the accuracy and relevance of the results of the comprehensive assessment depend precisely on the quality of data and the models used.

Also, data related to the distribution network of district heating systems was collected and shown on the map of Croatia.

The following two heating and cooling scenarios were defined for the purpose of cost-benefit analysis:

- **baseline scenario**, including a description of the current supply and its further trends over time, as well as information on how useful heating/cooling energy needs are currently being met and the assumptions on how they are to be met in the future, based on current knowledge, technological development and policy measures. This scenario is viewed as a reference scenario for identifying changes in the economic effects resulting from other scenarios;
- **alternative scenario**, based on previously determined technical potential. Alternative scenarios are proposed to be defined so that as much useful energy required for heating/cooling as possible (maximum scope) may be covered by each of the proposed solutions for efficient heating/cooling.

The main outcome of the cost-benefit analysis consists in **the most cost-efficient solutions for meeting heating and cooling needs**.

Definitions of the individual types of potential are provided below:

- **TECHNICAL POTENTIAL** – the amount of useful energy required, expressed in MWh/year, which could be covered by a technological solution or met from an estimated energy resource, taking into account its maximum achievable penetration over the time observed, considering technical and practical limitations (topographic limitations, environmental, and land-use

constraints), without taking into account economic criteria. Technical potential may be expressed in MWh/year or MW.

- ECONOMIC POTENTIAL – a subset of technical potential that is economically cost-effective compared with conventional supply-side energy resources. Economic potential may be expressed in MWh/year or MW.
- COST-BENEFIT POTENTIAL

A diagram of the methodology used for comprehensive assessment is provided below.

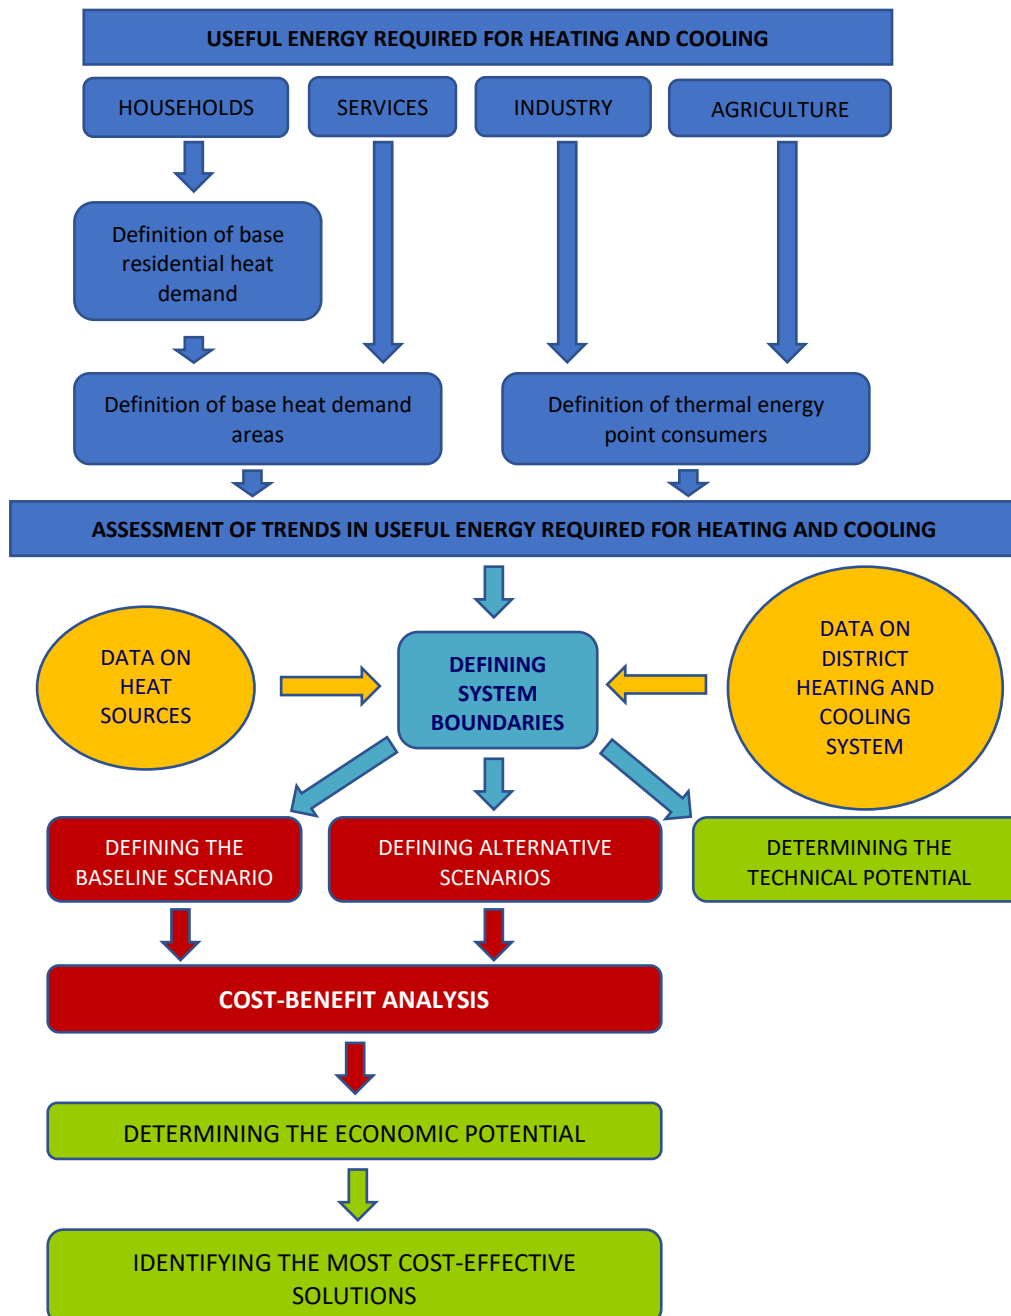

Figure 0.1: Diagram of the methodology for comprehensive assessment development

## b) Input data

Given that trends in the building stock and, consequently, the energy consumption in those buildings, are predominantly affected by changes in the population size, Croatia's demographic profile in 2019 serving as the basis for all further analyses is presented first in this chapter. Next, an overview of the national building stock is provided with data on the useful heated floor area for the residential building stock (household sector) and the non-residential building stock (service sector). It is important to note that all input and output data within this chapter are specified at the level of municipalities, cities or towns, and City of Zagreb districts.

### b.1) Croatia's projected population size in 2019

Given that the latest census in Croatia took place in 2011, population projections for 2019 were analysed in the Comprehensive Assessment. The projection of demographic trends in Croatia was taken from an analysis conducted by the Institute of Economics in Zagreb [17], which used the cohort component method according to Rowland's methodology to make population projections for an open population. The following variants were analysed:

- **Variant 1**
  - includes constant fertility;
  - foresees rising life expectancy for both sexes;
  - foresees a slowdown in emigration.
- **Variant 2**
  - includes an increase in the total fertility rate;
  - foresees rising life expectancy for both sexes;
  - foresees a slowdown in emigration.
- **Variant 3**
  - includes a greater increase in the total fertility rate;
  - foresees rising life expectancy for both sexes;
  - foresees less emigration compared to previous variants.

The projection of population size was made at the level of municipalities, cities or towns, and City of Zagreb districts. However, for the sake of simplicity, the table below contains the projected number of inhabitants for 2019 at county level. All further analyses included in the Comprehensive Assessment were based on Variant 2.

Table 0.1: Croatia's projected population size for 2019 by county

County name		Variant 1	Variant 2	Variant 3
1	Zagreb County	305 862	305 975	306 214

## b.2) Overview of the national building stock

An overview of the total national building stock is provided in the table below, while a detailed breakdown of how data in the table were obtained is available in the subchapters below, separately for each sector.

Table 0.2: National building stock by county

Overview of the national building stock					
County name		Total useful floor area of the heated part of the building [m <sup>2</sup> ]			Share [%]
		Residential buildings	Non-residential buildings	Total	
1	Zagreb County	9 261 485	2 424 273.00	10 490 100	6.29%
2	Krapina-Zagorje	3 684 540	952 821.00	6 023 845	3.61%
3	Sisak-Moslavina	5 229 179	858 898.00	4 203 951	2.52%
4	Karlovac	3 686 192	973 555.00	4 753 146	2.85%
5	Varaždin	4 968 459	1 720 080.00	6 389 353	3.83%
6	Koprivnica-Križevci	3 571 894	936 997.00	5 417 187	3.25%
7	Bjelovar-Bilogora	3 624 571	628 762.00	5 890 970	3.53%
8	Primorje-Gorski Kotar	9 585 069	3 145 783.00	9 547 308	5.73%
9	Lika-Senj	1 634 119	384 301.00	2 327 446	1.40%
10	Virovitica-Podravina	2 560 529	442 965.00	7 704 870	4.62%
11	Požega-Slavonia	2 320 386	651 126.00	2 036 609	1.22%
12	Slavonski Brod-Posavina	4 588 728	999 844.00	7 708 570	4.62%
13	Zadar	6 026 552	1 269 243.00	7 297 074	4.38%

## b.2.1) Overview of the national building stock – household sector

As part of the Comprehensive Assessment, the total useful floor area of the heated [building] part was determined separately for family houses and for multi-apartment buildings at the level of municipalities, cities or towns, and City of Zagreb districts. However, for the sake of simplicity, the data below is presented at county level.

The residential building stock calculation was based on data, as reported in the 2011 Croatian census of population, households and dwellings, concerning occupied dwellings according to the year of construction, building type and number of households, as well as on the 2010–2018 construction industry statistical reports. The residential building stock is divided into family houses and multi-apartment buildings, with family houses including buildings with one and two dwellings, while multi-apartment buildings include all buildings with three and more dwellings, as well as residences of communities and dwellings in non-residential buildings. A change in the 2011–2019 residential building stock was determined based on building permits issued between 2010 and 2018, minus the share of temporarily and permanently vacant dwellings in the total stock. Completed buildings follow the trend of issued building permits with a one-year delay, so the total floor area of the completed buildings is 7.75% smaller than the building area for which the building permits were issued. Dwellings excluded from fund statistics due to registered demolition or conversion, which on average account for less than 5% of the area of new constructions, are not excluded from the building stock, so a deviation is possible in the actual number and dwelling area. Further errors may also arise from incomplete sources of data regarding demolished dwellings, a lack of records on vacant dilapidated dwellings that are no longer fit for housing and changes in the use of the dwelling (e.g. if it is used for non-residential purposes). In addition, the large share of temporarily vacant dwellings in the total fund, which has doubled since the 2011 census and continues to increase, has individually the strongest impact on the number of permanently occupied dwellings, with the greatest deviations from the actual state of the stock occurring at the end of the census period.

The residential building stock by county presented in the table below show that family houses account for 64.75% of the total useful floor area of the heated part of buildings, while the remaining 35.25% refers to multi-apartment buildings.

Table 0.3: Residential building stock by county

## **B.2.2) Overview of the national building stock – service sector**

The total useful floor area of the heated part of service sector buildings was taken from the IEC database. The database includes all energy performance certificates issued since 1 October 2017, while data on the certificates issued before that date were kept by the Ministry of Physical Planning, Construction and State Assets in an Excel file. All the available data were analysed to obtain the total useful floor area of the heated part of service sector buildings by type of non-residential building.

According to the *Rules governing energy audits and energy performance certification of buildings* (NN 88/17) [18], all public buildings exceeding 250 m<sup>2</sup> in total floor area must be energy certified. Hence, it was impossible to analyse service sector buildings with a floor area of less than 250 m<sup>2</sup>. In addition, the analysis is based on the assumption that most other public buildings (> 250 m<sup>2</sup>) have been energy certified.

The *Rules governing energy audits and energy performance certification of buildings* (NN 88/17) [18] define the following types of non-residential buildings in the service sector:

- office buildings,
- educational buildings,
- hospitals,
- hotels and restaurants,
- sports halls,
- wholesale and retail trade buildings,
- other non-residential buildings heated to a temperature of +18 °C or higher (e.g. traffic and communication buildings, terminals, stations, post offices, telecommunications buildings, buildings for artistic and cultural activities and entertainment, museums, libraries),

so this breakdown of non-residential buildings will be used in the rest of the Comprehensive Assessment.

As part of the Comprehensive Assessment, the total useful floor area of the heated part of all non-residential building types referred to above was determined at the level of municipalities, cities or towns, and City of Zagreb districts. However, for the sake of simplicity, the data below are presented at county level.

Table 0.4: Non-residential building stock by county

<b>SERVICES – Overview of the national building stock</b>

<b>TOTAL</b>		<b>8 221 424.00</b>	<b>5 774 746.00</b>	<b>2 587 510.00</b>	<b>5 006 047.00</b>	<b>1 396 291.00</b>	<b>7 362 458.00</b>	<b>7 462 588.00</b>	<b>37 811 064.00</b>

Data presented in the table above show office buildings accounting for the largest, 21.74% share in the total useful floor area of the heated part of the non-residential building stock, followed by other non-residential buildings (19.74%), shops (19.47%), educational buildings (15.27%), hotels and restaurants (13.24%), and hospitals (6.84%), with sports halls accounting for the smallest share (3.69%).

*Additionally, based on data in the IEC database, the useful floor area of the heated part of service sector buildings was determined according to the energy products used for heating, cooling and DHW preparation, as shown in the tables annexed to this document (Annexes – Part 1: Table 0.1;*

Table 0.2.; Table 0.3:). Floor area was determined according to the energy products used for each municipality, city or town, and City of Zagreb district. However, for the sake of simplicity, the tables include only county-level data.

## **DIO I. OVERVIEW OF HEATING AND COOLING**

---

# 1 ANNUAL USEFUL ENERGY DELIVERED AND REQUIRED FOR HEATING/COOLING BY SECTOR

This chapter deals with an analysis of the 2019 energy delivered for heating, domestic hot water generation and cooling in Croatia for the following end-use consumption sectors or sub-sectors:

- **household sector:**
  - family houses,
  - multi-apartment buildings,
- **service sector:**
  - public buildings,
  - educational buildings (kindergartens, primary schools, secondary schools, universities),
  - hotels,
  - hospitals,
  - shops,
  - office buildings,
  - other,
- **industry:**
  - breakdown by key activity, e.g. cement industry, cellulose and paper, metallurgy.

It is important to note that, in the rest of the study, the terms delivered/useful **energy for heating** will include the energy for heating and domestic hot water generation!

In the household and service sectors, the terms heating/cooling refer exclusively to the heating/cooling of the building space and DHW preparation!

In the industrial sector, the terms heating/cooling refer to the heating/cooling of the building space, DHW preparation, as well as to heating / cooling / DHW preparation for industry processes.

## 1.1 CROATIA'S ENERGY BALANCE IN 2019

The following is an overview of final energy consumption by individual sectors and by energy products, according to data provided in Energy in Croatia 2019.

### 1.1.1 TOTAL FINAL ENERGY CONSUMPTION BY SECTOR

According to the guidance provided by the **Joint Research Centre (JRC)** [1] in 2015, it is necessary to determine the useful energy required for heating and cooling in the following main sectors:

- households (residential buildings),
- services (non-residential buildings),
- industry,
- agriculture.

According to [2], the Comprehensive Assessment must include household, service and industrial sectors, as well as any other sector that individually accounts for more than 5% of the total national useful heating or cooling demand.

In accordance with Energy in Croatia 2019 [3], final energy consumption trends for the three main end-use sectors: industry, transport and general consumption between 2015 and 2019 are provided in tabular form. General consumption refers to energy consumption by households, services, agriculture and construction.

It can be observed that the share of agriculture and construction sectors in the total final energy consumption was less than 6% in 2019.

Table I.1: Final energy consumption in Croatia, 2019

FINAL ENERGY CONSUMPTION		2015	2016	2017	2018	2019	2019 – consumption share [%]	
Industry	[GWh]	11 227.78	11 194.44	12 355.56	12 394.44	<b>12 427.78</b>	15.49	
Transport	[GWh]	24 547.22	25 197.22	27 233.33	27 094.44	<b>28 288.89</b>	35.26	
General consumption	Households	[GWh]	28 244.44	28 013.89	27 819.44	26 730.56	<b>26 030.56</b>	32.44
	Services	[GWh]	8 555.56	8 791.67	9 227.78	9 369.44	<b>9 458.33</b>	11.79
	Agriculture	[GWh]	2 677.78	2 716.67	2 680.56	2 733.33	<b>2 761.11</b>	3.44
	Construction	[GWh]	1 155.56	1 125.00	1 111.11	1 200.00	<b>1 266.67</b>	1.58
<b>TOTAL</b>		<b>76 408.33</b>	<b>77 038.89</b>	<b>80 427.78</b>	<b>79 522.22</b>	<b>80 233.33</b>	<b>100.00</b>	

Raspodjela ukupn neposredne potrošnje energije po sektorima u 2019.

Figure I.1: Distribution of total final energy consumption by sector in 2019 (Source: Energy in Croatia 2019)

CROATIAN	ENGLISH
Raspodjela ukupn neposredne potrošnje energije po sektorima u 2019.	Distribution of total final energy consumption in 2019
Poljoprivreda	Agriculture
Građevinarstvo	Construction
Industrija	Industry
Promet	Transport
Kućanstva	Households
Usluge	Services

Accordingly, the following sectors are analysed in this Comprehensive Assessment:

- **households** (residential buildings),
- **services** (non-residential buildings),
- **industry**.

The total final energy consumption in household, service and industrial sectors amounted to **47 916.67 GWh in 2019**. The final energy consumption was the highest in the household sector (54.32%), followed by industry (25.94%) and services (19.74%).

Table I.2: Final energy consumption in Croatia, 2019

FINAL ENERGY CONSUMPTION		2015	2016	2017	2018	2019	2019 – consumption share [%]
Households	[GWh]	28 244.44	28 013.89	27 819.44	26 730.56	<b>26 030.56</b>	54.32
Services	[GWh]	8 555.56	8 791.67	9 227.78	9 369.44	<b>9 458.33</b>	19.74

<b>TOTAL</b>		<b>48 027.78</b>	<b>48 000.00</b>	<b>49 402.78</b>	<b>48 494.44</b>	<b>47 916.67</b>	<b>100.00</b>

Raspodjela potrošnje energije po sektorima u 2019.

Figure I.2: Distribution of total final energy consumption by sector in 2019 (Source: Energy in Croatia 2019)

CROATIAN	ENGLISH
Raspodjela potrošnje energije po sektorima u 2019.	Distribution of energy consumption by sector in 2019
Industrija	Industry
Kućanstva	Households
Usluge	Services

In accordance with the guidance [1], **transport, agriculture and construction sectors are excluded from further analysis.**

In order to achieve greater accuracy, the three sectors (households, services and industry) are further divided into sub-sectors. For instance, a distinction is made between two sub-sectors, family houses and multi-apartment buildings, in the household sector. The energy consumption for heating purposes is typically lower in the case of a dwelling within a multi-apartment building than the energy consumption of a family house.

### 1.1.2 ENERGY BALANCE ACCORDING TO THE EUROSTAT METHOD – 2019

The following two balances for 2018 and 2019 are presented in Chapter 11, at the end of Energy in Croatia 2019 [3]:

- Energy balances according to the IAE method,
- Energy balances according to the Eurostat method,

specifying, among other things, the shares of individual energy products in the total final energy consumption of a particular sector (households, services, industry).

#### 1.1.2.1 HOUSEHOLD SECTOR

In accordance with Energy in Croatia 2019 [3], total final energy consumption in the household sector amounted to **26 030.56 GWh** in 2019.

According to the Eurostat method, total final energy consumption in the household sector was **25 869.77 GWh** in 2019.

Table I.3: HOUSEHOLD SECTOR – Distribution of total final energy consumption by energy product according to the Eurostat method, 2019

HOUSEHOLD SECTOR									
Energy balance for 2019 – Eurostat	Electricity	DHS	Natural gas	Fuel oil	LPG	Woody biomass	Solar energy	Lignite	TOTAL
Total final energy consumption [1 000 toe <sup>3</sup> /a] *	533.6	109.6	459.1	51.8	48.7	1 007.9	10.8	2.9	<b>2 224.4</b>
Total final energy consumption [GWh/a]	6 205.77	1 274.65	5 339.33	602.43	566.38	11 721.88	125.60	33.73	<b>25 869.77</b>
Share [%]	23.99	4.93	20.64	2.33	2.19	45.31	0.49	0.13	<b>100.00</b>

\* 1 000 toe = 11.63 GWh

It can be observed that woody biomass (45.31%) had the highest share in Croatia's 2019 consumption, followed by electricity (23.99%) and natural gas (20.64%). The share of energy delivered by district heating systems in the total final energy consumption stood at a mere 4.93%. Of the fossil fuels used in addition to natural gas, the household sector uses fuel oil (2.33%) and liquefied petroleum gas or LPG (2.19%).

SEKTOR KUĆANSTVA - raspodjela ukupne neposredne potrošnje energije u 2019. po EUROSTAT metodi po energentima

Prirodni plin	Natural gas
Loživo ulje	Fuel oil
UNP	LPG
Drvena biomasa	Woody biomass
Sunčeva energija	Solar energy
Geotermalna energija	Geothermal energy
Lignit	Lignite

### 1.1.2.2 SERVICE SECTOR

According to Energy in Croatia 2019 [3], total final energy consumption in the service sector amounted to **9 458.33 GWh** in 2019.

Total 2019 final energy consumption in the service sector, according to the Eurostat method, was **9 579.63 GWh**.

Table I.4: SERVICE SECTOR – Distribution of the total final energy consumption by energy product according to the Eurostat method, 2019

SERVICE SECTOR									
Energy balance for 2019 – Eurostat	Electricity	DHS	Natural gas	Fuel oil	LPG	Woody biomass	Solar energy	Geothermal energy	TOTAL
Total final energy consumption [1 000 toe <sup>4</sup> /a] *	516.00	36.80	208.80	27.50	13.70	12.40	4.60	3.90	<b>823.70</b>
Total final energy consumption [GWh/a]	6 001.08	427.98	2 428.34	319.83	159.33	144.21	53.50	45.36	<b>9 579.63</b>
Share [%]	62.64	4.47	25.35	3.34	1.66	1.51	0.56	0.47	<b>100.00</b>

\* 1 000 toe = 11.63 GWh

It can be observed that electricity (62.64%) had the highest share in Croatia's service sector consumption in 2019, followed by natural gas (25.35%). The share of energy delivered by district heating systems in the total final energy consumption stood at a mere 4.47%. Of the fossil fuels used in addition to natural gas, the service sector uses fuel oil (3.34%) and LPG (1.66%). The share of renewable energy delivered amounted to a total of 2.54%, with the share of woody biomass standing at 1.51%, solar energy at 0.56% and geothermal energy at 0.47%.

<sup>4</sup> toe – 1 tonne of oil equivalent – 1 000 toe = 11.63 GWh.

### 1.1.2.3 INDUSTRIAL SECTOR

According to Energy in Croatia 2019 [3], total final energy consumption in the industrial sector amounted to **12 427.78 GWh** in 2019.

Total 2019 final energy consumption in the household [sic – likely editing error, instead of: industrial] sector, according to the Eurostat method, was **13 908.32 GWh**.

Table I.5: INDUSTRIAL SECTOR – Distribution of the total final energy consumption by energy product according to the Eurostat method, 2019

Energy balance for 2019 – Eurostat	Total final energy consumption [1 000 toe/a] *	Total final energy consumption [GWh/a]	Share [%]
Hard coal	46.60	541.96	3.90
Coke	22.00	255.86	1.84
Lignite	7.70	89.55	0.64
LPG	11.10	129.09	0.93

## 1.2 ANNUAL ENERGY DELIVERED FOR HEATING/COOLING BY SECTOR

The sectoral distribution of the annual energy delivered for heating/cooling in Croatia in 2019 is provided in tabular form. It is evident that most energy for heating/cooling purposes was delivered to the household sector (62.46%), followed by the industrial sector (20.07%) and the service sector (17.55%).

Table I.6: Total annual energy delivered for heating/cooling in Croatia by sector, 2019

Sector name	Total annual energy delivered for heating/cooling [GWh/a]	Share [%]

USLUGE	SERVICES

### 1.2.1 HOUSEHOLD SECTOR

The household sector refers to residential buildings, comprising family houses and multi-apartment buildings.

NOTE: Heating refers to space heating and domestic hot water generation!

#### 1.2.1.1 TOTAL ENERGY DELIVERED FOR HEATING/COOLING

The total energy delivered to Croatia's household sector was modelled down to the level of individual municipalities, cities or towns, and City of Zagreb districts (17 city districts), including the following energy products in the model:

- electricity,
- DHS (district heating system),
- natural gas,
- fuel oil,
- liquefied petroleum gas,
- firewood,
- wood pellets / wood chips / briquettes,
- solar energy (solar collectors),
- energy taken from the environment using heat pumps.

The annual consumption of lignite was excluded from the model because of the unknown distribution of lignite consumption at the level of individual municipalities, cities or towns, and City of Zagreb districts. Also, the model of delivered energy includes the energy taken from the environment using heat pumps, which is not included in the total 2019 final energy consumption of the household sector according to the Eurostat method.

The total 2019 final energy consumption in the household sector was modelled at **26 088.45 GWh**. This amount differs slightly from the total final consumption in the household sector according to the Eurostat method (25 869.77 GWh) precisely due to the exclusion of lignite and inclusion of energy taken from the environment using heat pumps.

Only the energy delivered to the household sector for space heating/cooling and DHW preparation was excluded from the total delivered energy in the next step.

#### MODEL OF TOTAL ANNUAL ENERGY DELIVERED FOR SPACE HEATING WITHOUT RENEWABLE ENERGY TAKEN FROM THE ENVIRONMENT USING HEAT PUMPS

The total 2019 final energy consumption in the household sector was modelled at **25 920.18 GWh** (excluding lignite consumption and energy taken from the environment using heat pumps).

The model put the total annual energy delivered for space heating/cooling and DHW preparation at **20 759.36 GWh**, which means that **80.09% of the total energy delivered to the household sector** in Croatia is consumed **for space heating/cooling and DHW preparation** (heating/cooling). The remaining energy delivered is used for other non-heating energy needs (cooking, lighting, operation of electric household appliances).

Table I.7: HOUSEHOLD SECTOR – Distribution of total energy delivered (without renewable energy for space heating taken from the environment using heat pumps)

HOUSEHOLD SECTOR	Family houses	Multi-apartment buildings	TOTAL	Share [%]
Annual energy delivered for space heating/cooling and DHW preparation [GWh/a]	14 400.06	6 359.30	<b>20 759.36</b>	<b>80.09</b>
Annual energy delivered for other energy needs (cooking, lighting, operation of el. appliances) [GWh/a]	3 464.88	1 695.94	<b>5 160.82</b>	<b>19.91</b>
<b>Total annual energy delivered [GWh/a]</b>	<b>17 864.94</b>	<b>8 055.24</b>	<b>25 920.18</b>	<b>100.00</b>
<i>Share [%]</i>	<i>68.92</i>	<i>31.08</i>	<i>100.00</i>	

#### SEKTOR KUĆANSTVA - raspodjela ukupne isporučene energije

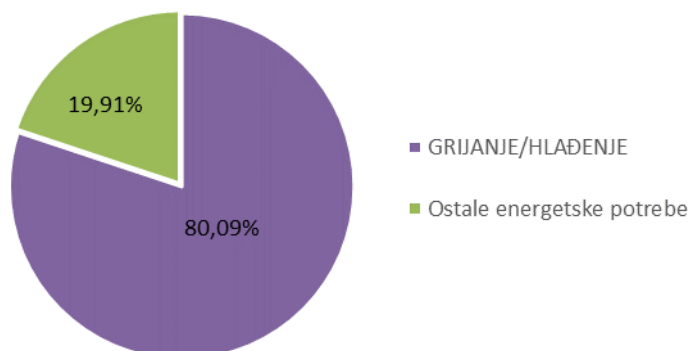

Figure I.7: HOUSEHOLD SECTOR – Distribution of total energy delivered

CROATIAN	ENGLISH
SEKTOR KUĆANSTVA - raspodjela ukupne isporučene energije	HOUSEHOLD SECTOR – Distribution of total energy delivered
GRIJANJE/HLAĐENJE	HEATING/COOLING
Ostale energetske potrebe	Other energy needs

Family houses use 69.37% of the total energy delivered for space heating/cooling and DHW preparation, while the remaining 30.63% is used by multi-apartment buildings, as expected in view of the ratio of the total useful floor area of the heated part of family houses to that of multi-apartment buildings (see Table I.8:).

Table I.8: HOUSEHOLD SECTOR – Distribution of the total energy delivered for space heating/cooling and DHW preparation by building type

HOUSEHOLD SECTOR	Family houses	Multi-apartment buildings	TOTAL
Annual energy delivered for space heating/cooling and DHW preparation [GWh/a]	14 400.06	6 359.30	<b>20 759.36</b>

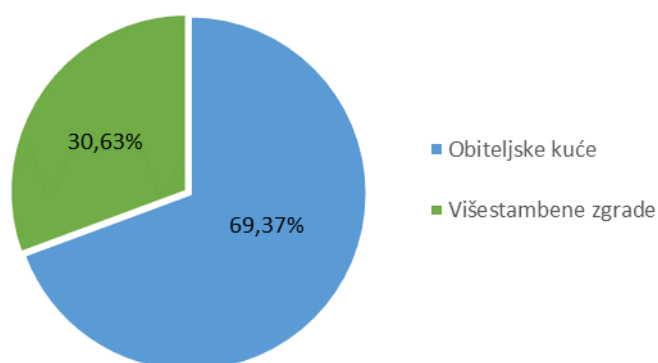

Figure I.8: HOUSEHOLD SECTOR – Distribution of the total energy delivered for space heating/cooling and DHW preparation by building type

CROATIAN	ENGLISH
SEKTOR KUĆANSTVA - raspodjela ukupne isporučene energije za potrebe grijanja/hlađenja prostora i pripreme PTV-a prema vrsti zgrade	HOUSEHOLD SECTOR – Distribution of the total energy delivered for space heating/cooling and DHW preparation by building type
Obiteljske kuće	Family houses
Višestambene zgrade	Multi-apartment buildings

Given that delivered energy in the templates (in Excel file format) prepared by the European Commission includes:

- all energy entering the building through the system boundary (electricity, natural gas, LPG, fuel oil),
- renewable energy entering through the system boundary (e.g. biomass),
- energy from renewable energy sources generated on the site of the building (e.g. heat generated on-site using solar collectors, heat taken from the environment using heat pumps),

heat taken from the environment using heat pumps also needs to be included in the balance of delivered energy. When it comes to heat pumps, only the electricity used to drive compression heat pumps is currently included in the balance.

Where electricity is used for space heating in the household sector, it is important for the model to differentiate between direct electric resistance space heating (electric heaters, electric boilers) and space heating using compression heat pumps. Each municipality, city or town was assigned to the coastal or the continental part of Croatia to model electricity for space heating purposes. Percentage shares were obtained for the use of compression heat pumps and direct electric resistance space heating in the household sector based on the surveys conducted.

When it comes to electricity used for space heating, around 70% of the electricity consumed in the coastal part of Croatia is generated by compression heat pumps, while 30% is accounted for by the standard electric resistance heating system (electric heaters, electric boilers). In the continental part of Croatia, this ratio is somewhat less favourable. The distribution of electricity consumption for space heating by technology used is certainly important for determining the annual thermal energy needs for heating.

Table I.9: HOUSEHOLD SECTOR – Distribution of the electricity consumption for space heating

HOUSEHOLDS	Share of electricity consumption for space heating, [%]	
	Space heating – compression heat pump	Space heating – direct electric resistance heating
Continental Croatia	3.00	97.00
Coastal Croatia	18.83	81.17

Table I.10: HOUSEHOLD SECTOR – Distribution of the electricity consumption for space heating

HOUSEHOLD SECTOR	Total annual energy delivered for space heating [GWh/a]				TOTAL
	Family houses		Multi-apartment buildings		
	Space heating	Space heating – HP	Space heating	Space heating – HP	
Electricity	71.94	115.01	93.83	197.44	<b>478.23</b>

**In the rest of the study, delivered energy will include all the forms of energy mentioned, also including the energy for space heating taken from the environment using heat pumps.**

#### MODEL OF TOTAL ANNUAL DELIVERED ENERGY WITH RENEWABLE ENERGY FOR SPACE HEATING TAKEN FROM THE ENVIRONMENT USING HEAT PUMPS

The total 2019 final energy consumption in the household sector was modelled at **26 088.45 GWh** (excluding lignite consumption and including energy taken from the environment using heat pumps).

The total annual energy delivered for space heating/cooling and DHW preparation obtained by the model was **20 927.63 GWh**, which means that **80.22% of the total energy delivered to the household sector** in Croatia is consumed **for space heating/cooling and DHW preparation** (heating/cooling). The remaining energy delivered is used for other non-heating energy needs (cooking, lighting, operation of electric household appliances).

Table I.11: HOUSEHOLD SECTOR – Distribution of the total energy delivered (with renewable energy for space heating taken from the environment using heat pumps)

HOUSEHOLD SECTOR	Family houses	Multi-apartment buildings	TOTAL	Share [%]
Annual energy delivered for space heating/cooling and DHW preparation [GWh/a]	14 462.08	6 465.55	20 927.63	80.22

### 1.2.1.2 DISTRIBUTION OF TOTAL ENERGY DELIVERED FOR HEATING/COOLING BY PURPOSE AND SYSTEM TECHNOLOGY

#### DISTRIBUTION OF TOTAL ENERGY DELIVERED FOR HEATING/COOLING BY PURPOSE AND SYSTEM TECHNOLOGY, WITH RENEWABLE ENERGY FOR SPACE HEATING TAKEN FROM THE ENVIRONMENT USING HEAT PUMPS

An analysis of the total energy delivered by purpose (heating / cooling / DHW preparation) produces the following distribution of **20 927.63 GWh** in total annual energy delivered for space heating/cooling and DHW preparation in the household sector:

- **79.44% for space heating** (16 625.51 GWh/a),
- **1.48% for space cooling** (310.68 GWh/a),
- **19.07% for DHW preparation** (3 991.44 GWh/a).

Table I.13: HOUSEHOLD SECTOR – Distribution of total energy delivered by purpose (with renewable energy taken from the environment using heat pumps for space heating)

2019	HOUSEHOLDS			TOTAL	Share [%]
	Space heating	Space cooling	DHW preparation

#### SEKTOR KUĆANSTVA - raspodjela ukupne isporučene energije prema namjeni

Figure I.11: HOUSEHOLD SECTOR – Distribution of total energy delivered by purpose (with renewable energy taken from the environment using heat pumps for space heating)

CROATIAN	ENGLISH
SEKTOR KUĆANSTVA - raspodjela ukupne isporučene energije prema namjeni	HOUSEHOLD SECTOR – Distribution of total energy delivered by purpose
Grijanje prostora	Space heating
Hlađenje prostora	Space cooling
Priprema PTV-a	DHW preparation

Electricity, DHS, natural gas, fuel oil, LPG, woody biomass (log wood, pellets/chips/briquettes) are used for **space heating in buildings** in the household sector. Heating of building space in the household sector is decentralised (individual split air-conditioning, individual stoves) and centralised (boilers, heat pumps, DHS). The distribution of the total electricity delivered for space heating by type of building is provided in the table.

Furthermore, 56.50% of the total energy delivered for space heating in the household sector is consumed using a room-based, that is, a decentralised space heating system (individual stoves, split air conditioning). Merely 43.50% of the total energy delivered for space heating is consumed using district heating systems, so decentralised (room-based) space heating systems still account for a large share in Croatia.

Table I.14: HOUSEHOLD SECTOR – Distribution of total energy delivered for space heating by type of space heating system technology (with renewable energy taken from the environment using heat pumps for space heating)

HOUSEHOLD SECTOR	Total annual energy delivered for space heating [GWh/a]			Share [%]
	room-based	centralised	TOTAL	
Family houses	6 823.25	4 871.51	<b>11 694.76</b>	70.34
Multi-apartment buildings	2 570.96	2 359.79	<b>4 930.75</b>	29.66
<b>TOTAL</b>	9 394.21	7 231.30	<b>16 625.51</b>	100.00
Share [%]	56.50	43.50	100.00

decentralni sustav grijanja	decentralised heating system
centralni sustav grijanja	DHS

In the household sector, only electricity is used for **space cooling in buildings**, and space cooling is decentralised (individual split air conditioning) or centralised.

Approximately 85% of the total energy delivered for space cooling in the household sector is consumed using a room-based, that is, a decentralised space cooling (individual air conditioning), so decentralised (room-based) space cooling systems still account for a large share in Croatia.

Table I.15: HOUSEHOLD SECTOR – Distribution of total energy delivered for space cooling by type of space cooling system technology

HOUSEHOLD SECTOR	Total annual energy delivered for space cooling [GWh/a]			Share [%]
	room-based	centralised	TOTAL	

Family houses	157.68	27.83	<b>185.50</b>	59.71
Multi-apartment buildings	106.40	18.78	<b>125.17</b>	40.29

decentralni sustav grijanja	decentralised cooling system
centralni sustav grijanja	centralised cooling system

**Domestic hot water in the household sector** is generated using decentralised and centralised systems. The distribution of the total electricity delivered for DHW preparation by type of building is provided in the table. Family houses use 64.68% of the total energy delivered for DHW preparation, while the remaining 35.32% is used by multi-apartment buildings.

SEKTOR KUĆANSTVA - raspodjela godišnje isporučene energije za potrebe pripreme PTV-a prema vrsti zgrade

Međimurska	Međimurje
Grad Zagreb	City of Zagreb

The use of firewood (49.84%) prevails in Croatia's household sector, followed by natural gas (23.48%) and electricity (12.44%). Just 6.09% of the total energy delivered to the household sector for space heating/cooling purposes and DHW preparation was delivered by district heating systems, with the energy going exclusively to multi-residential buildings. Thermal energy generated in solar collectors for DHW preparation or space heating is negligible in view of the potential of solar radiation in the territory of Croatia. Of renewable energy sources, wood pellets / wood chips / briquettes are used, but their share in the total energy delivered for space heating/cooling and DHW preparation stands at a modest 3.59%. The share of renewable energy taken from the environment using heat pumps is 0.80%.

The distribution of the total electricity delivered for space cooling by type of building is provided in tabular form.

The following counties are the top consumers of electricity **for cooling in the household sector**:

1. City of Zagreb (19.33%),
2. Split-Dalmatia (8.76%),
3. Zagreb County (7.48%),
4. Osijek-Baranja (7.36%),
5. Primorje-Gorski Kotar (7.20%),
6. Istria (5.34%).

The use of firewood (58.70%) and natural gas (23.93%) for space heating prevails in Croatia's household sector. These energy products are followed by much smaller shares of DHS (5.73%), wood pellets / wood chips / briquettes (3.89%), fuel oil (3.51%) and electricity (2.91%). The share of renewable energy taken from the environment using heat pumps is just 1.01%.

Table I.22: HOUSEHOLD SECTOR – Distribution of total energy delivered for space heating by building type and energy product (with renewable energy taken from the environment using heat pumps for space heating)

HOUSEHOLD SECTOR	Total annual energy delivered for space heating [GWh/a]

SEKTOR KUĆANSTVA - raspodjela ukupne isporučene energije za potrebe grijanja prostora po energentima

Figure I.18: HOUSEHOLD SECTOR – Distribution of total energy delivered for space heating ,by energy product (with renewable energy taken from the environment using heat pumps for space heating)

CROATIAN	ENGLISH
SEKTOR KUĆANSTVA - raspodjela ukupne isporučene energije za potrebe grijanja prostora po energentima	HOUSEHOLD SECTOR – Distribution of total energy delivered for space heating by energy product
Električna energija	Electricity
CTS	DHS
Prirodni plin	Natural gas
Loživo ulje	Fuel oil
UNP	LPG
Ogrjevno drvo	Firewood
Drvni peleti/sječka/briketi	Wood pellets / wood chips / briquettes
Sunčeva energija (solarni kolektori)	Solar energy (solar collectors)
OIE preuzeta iz okoliša pomoću dizalica topline	RES taken from the environment using heat pumps

In the household sector, only electricity is used for **space cooling in buildings** in Croatia, and space cooling is decentralised (individual split air conditioning) or centralised.

**The use of electricity (45.33%) and natural gas (23.44%) for DHW preparation prevails** in Croatia's household sector. Firewood (16.84%) and DHS (8.05%) follow. Other energy products (solar energy, wood pellets / wood chips / briquettes, LPG, fuel oil) have negligible shares in DHW preparation. Merely 2.72% of the total annual energy delivered for DHW preparation is derived from solar collectors.

Table I.23: HOUSEHOLD SECTOR – Distribution of total energy delivered for DHW preparation by building type and energy product

SEKTOR KUĆANSTVA - raspodjela ukupne isporučene energije za potrebe pripreme PTV-a po energentima	HOUSEHOLD SECTOR – Distribution of total energy delivered for DHW preparation by energy product
Električna energija	Electricity
CTS	DHS
Prirodni plin	Natural gas
Loživo ulje	Fuel oil
UNP	LPG
Ogrjevno drvo	Firewood
Drvni peleti/sječka/briketi	Wood pellets / wood chips / briquettes
Sunčeva energija (solarni kolektori)	Solar energy (solar collectors)

### 1.2.2 SERVICE SECTOR

The energy delivered for heating, DHW preparation and cooling in the service sector is derived from:

- data on the heated area, location and building type available and determined from the IEC database;

data on the specific energy needed for heating, DHW preparation and cooling for different types of buildings and two climate zones (continental and coastal) taken from the study entitled *Determining minimum requirements for energy performance of buildings*, prepared by the EIHP for the Ministry of Physical Planning, Construction and State Assets, 2020 [19] - (Annexes:

- Table 0.4.; Table 0.5.; Table 0.6.);
- assumptions on the efficiency of the technology used, derived from the energy product used for heating, DHW preparation and cooling specified in the IEC database (Annexes: Table 0.7:); and
- available data obtained from distributors.

Based on such data, the energy delivered for heating, DHW preparation and cooling in Croatia's service sector has been calculated at **5 843.57 GWh/a**. A comparison of that consumption with the total service sector consumption provided in Energy in Croatia leads to a conclusion that the energy delivered for heating, cooling and DHW preparation accounts for 61.00% of the total energy delivered, while the remaining energy is consumed for other non-heating energy needs (cooking, lighting, operation of electrical appliances). A detailed presentation and distribution of the energy delivered are provided in the table and chart below.

Table I.24. SERVICE SECTOR – Energy delivered for heating, DHW preparation and cooling by energy product

Energy product	Heating [GWh/a]	DHW preparation [GWh/a]	Cooling [GWh/a]	Total [GWh/a]
LPG	121.38	18.70	–	<b>139.80</b>
Fuel oil	257.07	43.50	–	<b>300.29</b>
Natural gas	1 951.21	170.49	–	<b>2 121.42</b>
Total renewable energy sources*	142.73	56.15	–	<b>223.53</b>
DHS	374.19	34.54	–	<b>408.45</b>
Electricity	695.30	347.15	1 490.70	<b>2 503.24</b>

SEKTOR USLUGA – Raspodjela isporučene energije za grijanje, pripremu PTV-a i hlađenje	SERVICE SECTOR – Distribution of the energy delivered for heating, DHW preparation and cooling
Grijanje	Heating
PTV	DHW
Hlađenje	Cooling

In addition, the energy delivered for heating, DHW preparation and cooling was analysed for each municipality, city or town, and City of Zagreb district. However, for the sake of simplicity, the tables include only county-level data. The overall energy delivered for heating, DHW preparation and cooling by energy product and building type is presented below, while the energy delivered separately for each purpose (heating, DHW preparation and cooling) is provided in an annex to this document (Table 0.8: – Table 0.13:).

The following counties are the top consumers of total energy delivered for space heating, DHW preparation and cooling in the service sector:

1. City of Zagreb (23.80%),
2. Split-Dalmatia (11.12%),
3. Istria (7.76%),
4. Primorje-Gorski Kotar (7.67%),
5. Zagreb County (6.88%),
6. Osijek-Baranja (6.31%).

In addition, most of the total energy delivered to the service sector is accounted for by non-residential buildings (20.33%), followed by office buildings (18.83%), trade buildings (18.74%), hotels and restaurants (15.56%), educational buildings (12.59%), hospitals (9.65%) and sports halls (4.54%).

An analysis of the total energy consumption by energy product reveals the consumption of electricity (43.35%) and natural gas (36.31%) to have the biggest share in the total energy consumption for space heating, DHW preparation and cooling, while the remaining energy products together (LPG, fuel oil, RES, DHS sources and other) account for just 20.34% of the total consumption.

Table I.25: SERVICE SECTOR – Energy delivered for heating, DHW preparation and cooling by building type at county level

### 1.2.3 INDUSTRIAL SECTOR

The exact 2019 annual consumption of the energy delivered to the industrial sector separately for each company was obtained from the Croatian Bureau of Statistics.

#### 1.2.3.1 DEFINING THE INDUSTRIAL SECTOR AS PART OF THE COMPREHENSIVE ASSESSMENT

The annual consumption of all energy products in 2019 for every company, as well as their National Classification of Activities (NCA) code, is stated separately in the Excel file provided by the Croatian Bureau of Statistics. Each company has been assigned an actual address, used subsequently to determine the geographical coordinates (latitude and longitude) of the biggest consumers.

In addition to the industry, the Croatian Bureau of Statistics also monitors other activities which are not part of the industry, so they have been dropped from further analysis.

All Croatian economic activities are classified into defined divisions from 01 to 99. Each division belongs to one of a total of 14 main sections of activities, marked with codes A to N.

The NCA code used for determining the type of activity consists of 4 digits in total. The first two digits define the main section or division of activity, while the last two digits define the group within a particular division.

For instance, a company with the code NCA 10.81 belongs to the main section C – Manufacturing, the Manufacture of food products division (10 as the two initial digits), the Manufacture of sugar group (the remaining two digits 81).

An overview of the main sections of activities with related divisions is provided in tabular form (Table I.27:). The Comprehensive Assessment takes into account the following two main sections in the industrial sector:

A – Mining and quarrying

B – Manufacturing

with a few exceptions, which do not belong in the industrial sector (Table I.28:):

- 05 – Mining of coal and lignite → belongs in the ENERGY sector;
- 06 – Extraction of crude petroleum and natural gas → belongs in the ENERGY sector;
- 19 – Manufacture of coke and refined petroleum products → belongs in the ENERGY SECTOR;
- 33 – Repair and installation of machinery and equipment → belongs in the SERVICE sector.

Table I.27: Overview of the main sections of activities with divisions

Section code	Section name	Division number	Taken into account
A	Agriculture, forestry and fisheries	01-03	NO
<b>B</b>	<b>Mining and quarrying</b>	<b>05-09</b>	<b>YES</b>
<b>C</b>	<b>Manufacturing</b>	<b>10-33</b>	<b>YES</b>
D	Electricity, gas, steam and air conditioning supply	35	NO
E	Water supply, sewerage, waste management and remediation activities	36-39	NO
F	Construction	41-43	NO
G	Wholesale and retail trade; repair of motor vehicles and motorcycles	45-47	NO
H	Transportation and storage	49-53	NO
I	Accommodation and food service activities	55-56	NO
J	Information and communication	59-63	NO
K	Financial and insurance activities	64-66	NO
L	Real estate activities	68	NO
M	Professional, scientific and technical activities	69-75	NO
N	Administrative and support service activities	77-82	NO

Section code	Section name	Division number	Taken into account
O	Public administration and defence; compulsory social security	84	NO
P	Education	85	NO
Q	Human health services and social work activities	86-88	NO
R	Arts, entertainment and recreation	90-93	NO
S	Other service activities	94-96	NO
T	Activities of households as employers; undifferentiated goods and services producing activities of households for own use	97-98	NO
U	Activities of extraterritorial organisations and bodies	99	NO

Table I.28: Overview of industrial sector divisions

Section code	Section name	Division number	Division name	Sector	Taken into account
<b>B</b>	<b>MINING AND QUARRYING</b>	<b>05</b>	<b>Mining of coal and lignite</b>	<b>ENERGY</b>	<b>NO</b>
		<b>06</b>	<b>Extraction of crude petroleum and natural gas</b>	<b>ENERGY</b>	<b>NO</b>
		07	Mining of metal ores	INDUSTRY	YES
		08	Other mining and quarrying	INDUSTRY	YES
		09	Mining support service activities	INDUSTRY	YES
<b>C</b>	<b>MANUFACTURING</b>	10	Manufacture of food products	INDUSTRY	YES
		11	Manufacture of beverages	INDUSTRY	YES
		12	Manufacture of tobacco products	INDUSTRY	YES
		13	Manufacture of textiles	INDUSTRY	YES
		14	Manufacture of wearing apparel	INDUSTRY	YES
		15	Manufacture of leather and related products	INDUSTRY	YES
		16	Manufacture of wood and of products of wood and cork, except furniture; manufacture of articles of straw and plaiting materials	INDUSTRY	YES
		17	Manufacture of paper and paper products	INDUSTRY	YES
		18	Printing and reproduction of recorded media	INDUSTRY	YES
		<b>19</b>	<b>Manufacture of coke and refined petroleum products</b>	<b>ENERGY</b>	<b>NO</b>
		20	Manufacture of chemicals and chemical products	INDUSTRY	YES
		21	Manufacture of basic pharmaceutical products and pharmaceutical preparations	INDUSTRY	YES
		22	Manufacture of rubber and plastic products	INDUSTRY	YES
		23	Manufacture of other non-metallic mineral products	INDUSTRY	YES
		24	Metal production	INDUSTRY	YES
		25	Manufacture of fabricated metal products, except machinery and equipment	INDUSTRY	YES
		26	Manufacture of computer, electronic and optical products	INDUSTRY	YES
		27	Manufacture of electrical equipment	INDUSTRY	YES
		28	Manufacture of machinery and equipment n.e.c.	INDUSTRY	YES
		29	Manufacture of motor vehicles, trailers and semi-trailers	INDUSTRY	YES
30	Manufacture of other transport equipment	INDUSTRY	YES		
31	Manufacture of furniture	INDUSTRY	YES		
32	Other manufacturing	INDUSTRY	YES		
<b>33</b>	<b>Repair and installation of machinery and equipment</b>	<b>SERVICES</b>	<b>NO</b>		

While section B is mining, all parts of mining which are not so-called energy mining (e.g. mining of coal and lignite, extraction of crude petroleum and natural gas) are also observed as a single branch of the industry (mining) in energy balances.

While manufacturing includes divisions from number 10 up to and including 32, division 19 – Manufacture of coke and refined petroleum products does not belong in the industrial sector but in the energy sector in energy balances.

Construction is also observed as a single branch of the industry but it has been dropped from further analysis, considering that the share of energy delivered in the total energy delivered used for heating and cooling is negligible and is of no interest for the comprehensive assessment.

### 1.2.3.2 OVERVIEW OF ENERGY PRODUCTS TAKEN INTO ACCOUNT IN THE INDUSTRIAL SECTOR

The annual consumption of all energy products in 2019 is stated separately for every company in the Excel file provided by the Croatian Bureau of Statistics. Upon the determination of the companies that belong in the industrial sector with regard to their activity, energy products used for heating/cooling were defined, and all energy products not used for heating/cooling have been dropped from further analysis. E.g. all energy products used in transport (petrol, diesel fuels) have been dropped from further analysis.

An overview of all energy products that companies use has been provided in tabular form, together with the energy product codes, units and the lower heating value of energy products, and also the indication of which energy products are taken into account for further analysis, that is, for determining the annual thermal energy needs for heating and cooling. In addition, the average degree of efficiency for combustion plants has been defined for energy products burned in combustion plants, to be used for the subsequent determination of useful thermal energy needs for heating.

Table I.29: INDUSTRIAL SECTOR – List of energy products taken into account

Energy product code	Energy product name	Unit	Lower heating value [kWh/unit]	Energy product taken into account for heating/cooling (YES/NO)	Degree of efficiency
11	Electricity	–	–	YES	–
15	Steam and water at temperatures lower than or equal to 200 °C	–	–	YES	–
16	Steam and water at temperatures higher than 200 °C	–	–	YES	–

In the industrial sector, electricity is used for the following needs, related to heating/cooling:

- heating in the production process;
- cooling in the production process using compression cooling unit;
- space cooling in office buildings using split air conditioning; and
- DHW preparation in office buildings using individual electric boilers.

In the industrial sector, network-distributed natural gas is used for the following heating/cooling-related needs:

- heating in the production process;
- heating of building space; and
- cooling in the production process (using gas absorption cooling unit).

The average values of the degree of efficiency of the sources of heating and cooling energy needed for determining useful thermal energy for heating/cooling in the case of electricity and natural gas are provided in tabular form.

Table I.30: INDUSTRIAL SECTOR – Use of electricity and natural gas as energy product for covering heating/cooling needs

Code	Energy product name	Needs	HEATING – degree of efficiency [–]	COOLING – energy efficiency ratio [–]
11	Electricity	Heating in the production process	0.99	–
		Cooling in the production process using compression cooling unit	–	3.00
		Space cooling in office buildings using split air conditioning	–	2.80
		DHW preparation in office buildings using individual electric boilers	0.99	–
51	Natural gas, network-distributed	Heating in the production process	0.87	–
		Heating of building space	0.91	–
		Cooling in the production process (gas absorption cooling unit)	–	1.10 <sup>7</sup>

<sup>6</sup> Used in the energy sector.

<sup>7</sup> EER of gas absorption cooling unit – ratio between the efficiency of the evaporator and the generator.

Naturally, in the industrial sector, electricity is used for motor drives, electrochemical purposes, powering of appliances (including IT equipment), lighting and other energy purposes, but the Comprehensive Assessment only takes into account that part of a certain energy product which is used for heating, DHW preparation and cooling.

### 1.2.3.3 TOTAL ENERGY DELIVERED TO THE INDUSTRIAL SECTOR

Within this study, it is important to distinguish between:

- **total energy delivered to the industrial sector** for the defined energy products, covering other needs in addition to heating/cooling; and
- **energy delivered for heating<sup>8</sup>/cooling.**

Based on the data provided by the Croatian Bureau of Statistics, **total energy delivered** and registered in Croatia in 2019 amounts to **8 981.44 GWh** for a total of **2 478 companies** that fall in the **industrial sector** according to their NCA code. Only the energy products defined in Chapter 1.2.3.2 have been taken into account.

It should be noted that the following two energy products:

- steam and water at temperatures lower than or equal to 200 °C, and
- steam and water at temperatures higher than 200 °C

are obtained through the following:

- supply directly from district heating systems (DHS);
- generation from industrial boiler rooms; and
- generation from industrial cogeneration installations.

When it comes to industrial boiler rooms and cogeneration installations, different types of energy products are used to generate steam and water (natural gas, fuel oil, waste, brown coal and lignite).

**Total number of industrial boiler rooms** in Croatia in 2019: **57**

**Total number of industrial cogeneration installations** in Croatia in 2019: **5**

More data on industrial boiler rooms and industrial cogeneration installations is available in the following chapters.

Total energy delivered in the industrial sector by county, with consumption referring to steam and water and not the energy product used to generate steam and water, is stated in Table I.31.: Of the specified amount of steam and water, the portion of energy needed for heating/cooling has been excluded to determine the useful energy for heating and cooling.

Electricity (38,60%) had for the highest share in industrial sector consumption, followed by network-distributed natural gas (23.93%) and petroleum coke (13.66%).

While consumption at the level of each company is known, due to data confidentiality and extensiveness it is not stated in this study at individual company level, but an overview at county level is provided.

---

<sup>8</sup> Heating refers to space heating and domestic hot water preparation.

### 1.2.3.4 TOTAL ENERGY DELIVERED TO THE INDUSTRIAL SECTOR FOR HEATING/COOLING

Total energy delivered for heating/cooling purposes to the industrial sector in Croatia amounted to **6 733.98 GWh** in 2019.

Most energy in the industrial sector is used for the purposes of heating in the production process (85.72%), while 8.61% of the total annual energy delivered for heating/cooling is used for space heating and DHW preparation. Space cooling and cooling for production process purposes account for only 5.67% of the total annual energy delivered for heating/cooling purposes.

Figure I.21: INDUSTRIAL SECTOR – Distribution of total annual energy delivered for heating/cooling by purpose

CROATIAN	ENGLISH
SEKTOR INDUSTRIJE - raspodjela ukupne godišnje isporučene energije za potrebe grijanja/hlađenja prema namjeni	INDUSTRIAL SECTOR – Distribution of total annual energy delivered for heating/cooling by purpose

Grijanje prostora i priprema PTV-a	Space heating and DHW preparation
Hlađenje prostora	Space cooling
Grijanje u procesu proizvodnje	Heating in the production process

Figure I.22: shows the distribution of total annual energy delivered for heating/cooling to the industrial sector by purpose and energy products.

The most widely used energy products for heating in the production process are:

- natural gas (1 724.45 GWh/a; 29.88%),
- petroleum coke (1 226.88 GWh/a; 21.25%),
- electricity (821.78 GWh/a; 14.24%),
- hard/brown coal and their briquettes (577.70 GWh/a; 10.01%),
- DHS (355.14 GWh/a; 6.15%).

Electricity is the main energy product used for cooling in the production process, with natural gas used to a certain extent.

For the following energy products:

- electricity,
- steam and water at temperatures lower than or equal to 200 °C,
- steam and water at temperatures higher than 200 °C, and
- network-distributed natural gas,

the Croatian Bureau of Statistics has provided data on the distribution of the total energy delivered by individual energy products, according to their purpose for each type of activity defined by its NCA code.

Due to the complexity and size of the table, this study does not include it in its entirety. The distribution of the total electricity delivered, using mill products and beer as examples, is provided in the table below.

Table I.34: Distribution of total electricity delivered according to needs, using manufacture of mill products and beer as examples

NCA code	Name	Electricity – share in the total energy delivered [-]							TOTAL
		Heat in the production process	Space and water heating/cooling in office buildings	Cooling in the production process	Electric motor	Electrochemical use	Appliances (including IT equipment) and lighting	Other energy purposes	
1061	Manufacture of mill products	0.0745	0.0005	0.0195	0.8303	0.0000	0.0752	0.0000	1.00
1105	Manufacture of beer	0.4546	0.0385	0.1444	0.3424	0.0016	0.0185	0.0000	1.00

The total energy delivered from individual energy products (electricity, steam and water at temperatures lower than or equal to 200 °C, steam and water at temperature higher than 200 °C, and network-distributed natural gas) has been distributed by needs, depending on their NCA code. For the purpose of further analysis, only the portion of energy delivered from individual energy products used for heating (heating for production process purposes or building space heating), DHW preparation and cooling (cooling for production process purposes or building space cooling) in the industrial sector has been taken into account.

Of the following total energy delivered to the industrial sector:

- electricity,
- steam and water at temperatures lower than or equal to 200 °C,
- steam and water at temperatures higher than 200 °C, and
- network-distributed natural gas,

only the energy delivered for heating/cooling purposes is shown below.

Electricity and natural gas are used for (see Table I.35: Table I.36):

- heating in the production process;
- space and water heating/cooling in related office buildings; and
- cooling in the production process (using absorption cooling unit).

It is evident that 35.23% of the total electricity delivered to the industrial sector is consumed for heating/cooling, while 64.77% is used for other purposes (motor drives, electrochemical purposes, powering of appliances including IT equipment, lighting and other energy purposes).

In the case of network-distributed natural gas, 99.89% of natural gas is used for heating/cooling.

Steam and water at temperatures lower than or equal to 200 °C and steam and water at temperatures higher than 200 °C are used for (Table I.37.; Table I.38.):

- heating in the production process; and
- space and water heating/cooling in related office buildings.

The delivered steam and water energy is mainly used for heating/cooling. In the Zadar County, there is a company using steam and water at temperatures lower than or equal to 200 °C, with the NCA code 0893. However, according to the Croatian Bureau of Statistics distribution of steam and water consumption, no delivered steam or water energy is used for heating/cooling, so the stated amount of steam and water has been categorised under other energy purposes.

Furthermore, in the case of all energy products (electricity, natural gas, steam and water at temperatures lower than or equal to 200 °C, and steam and water temperature higher than 200 °C), the already excluded amount of energy products for heating/cooling and DHW in the related office buildings needs to be divided further as follows:

- energy delivered for space heating in office buildings,
- energy delivered for space cooling in office buildings, and
- energy delivered for DHW preparation in office buildings

to determine separately the annual thermal energy needed for heating and cooling.

#### ELECTRICITY DISTRIBUTION – Space and water heating/cooling in office buildings

A portion of the total electricity delivered is used for space heating/cooling in office buildings, or for DHW preparation. In office buildings, DHW is mostly generated from individual electric boilers, space cooling is performed by compression cooling units (mostly split air conditioning), while electricity in the heating system is mostly used for powering circulation pumps in initial heating circuits. The distribution of consumption of electricity delivered to office buildings in the continental and the coastal part of Croatia is provided in tabular form. The figures have been defined based on the experience acquired in the process of conducting energy audits of office buildings and electricity consumption modelling, which forms a mandatory part of the *Report on a completed energy audit of the building* for the purpose of energy certification of buildings. As expected, in the coastal part of Croatia, more electricity is used for space cooling and less for space heating.

Table I.39: INDUSTRIAL SECTOR – Distribution of a portion of the total electricity delivered for space heating/cooling of offices and DHW preparation

INDUSTRY – related office buildings	Share of distribution of the consumption of electricity for space heating/cooling and DHW preparation [–]			
	Space heating	DHW	Space cooling	TOTAL
K – continental Croatia	0.1083	0.2052	0.6864	1.0000
P – coastal Croatia	0.0541	0.0560	0.8899	1.0000

Municipalities, cities or towns belong in continental Croatia when the average monthly external air temperature in the coldest month, according to meteorological data for the nearest competent weather station,  $\theta_{mm} \leq 3$  °C.

Municipalities, cities or towns belong in coastal Croatia when the average monthly external air temperature in the coldest month, according to meteorological data for the nearest competent weather station,  $\theta_{mm} > 3\text{ }^{\circ}\text{C}$ .

Table I.40: INDUSTRIAL SECTOR – Distribution of electricity delivered by counties

Share [%]		100.00	9.78	17.63	72.59

#### NATURAL GAS DISTRIBUTION – Space and water heating/cooling in office buildings

Where natural gas is used in related office buildings, the already excluded amount of natural gas for heating/cooling of space and water in office buildings is taken to be used exclusively for space heating of office buildings. Due to low DHW consumption in office buildings, DHW preparation is predominantly decentralised using individual electric boilers. Space cooling using natural gas combustion in office buildings is rare in Croatia.

#### STEAM AND WATER DISTRIBUTION – Space and water heating/cooling in office buildings

Where steam and water are used for heating/cooling and DHW preparation in office buildings, the entire amount of already excluded steam/water energy for heating/cooling and DHW preparation in office buildings is taken to be consumed exclusively for space heating of related office buildings.

**Total energy delivered to the industrial sector** in Croatia in 2019 amounted to **8 981.44 GWh** for a total of 2 479 [sic – likely editing error, instead of 2 478] companies which, according to their NCA code, belong to the industrial sector.

**Total energy delivered for heating/cooling purposes to the industrial sector** in Croatia amounted to **6 733.98 GWh** in 2019.

**Of the total 2019 energy delivered to the industrial sector, 74.98% was used for heating/cooling.**

## SEKTOR INDUSTRIJE - raspodjela ukupne isporučene energije

Figure I.23: INDUSTRIAL SECTOR – Distribution of total energy delivered

CROATIAN	ENGLISH
SEKTOR INDUSTRIJE - raspodjela ukupne isporučene energije	INDUSTRIAL SECTOR – Distribution of total energy delivered
GRIJANJE/HLAĐENJE	HEATING/COOLING
Ostale energetske potrebe	Other energy needs

An overview of energy delivered for heating/cooling is provided in tabular form (Table I.41:). It is evident that 94.33% of the total energy delivered to the industrial sector for heating/cooling is used for heating, with a mere 5.67% used for cooling.

## SEKTOR INDUSTRIJE - raspodjela ukupne isporučene energije za potrebe grijanja/hlađenja

Figure I.24: INDUSTRIAL SECTOR – Distribution of total annual energy delivered for heating/cooling

CROATIAN	ENGLISH
SEKTOR INDUSTRIJE - raspodjela ukupne isporučene energije za potrebe grijanja/hlađenja	INDUSTRIAL SECTOR – Distribution of total annual energy delivered for heating/cooling
GRIJANJE	HEATING
HLAĐENJE	COOLING

The amount of energy delivered for heating/cooling was the highest in the Osijek-Baranja County (15.62%), followed by the Istria County (14.81%) and the Split-Dalmatia County (14.13%).

The following counties are large consumers of the energy delivered for heating/cooling:

- **Osijek-Baranja County:** manufacture of paper, cement industry, processing of wood and wood products, manufacture of sugar, manufacture of oil, and manufacture of other non-metallic mineral products;
- **Istria County:** manufacture of other non-metallic mineral products, manufacture of motor vehicles, trailers and semi-trailers, and manufacture of tobacco products; and
- **Split-Dalmatia County:** manufacture of other non-metallic mineral products, printing and reproduction of recorded media, manufacture of rubber and plastic products, and manufacture of other transport equipment.

Table I.42: provides an overview of the number of industrial companies and the total energy delivered for heating/cooling in a total of five intervals of energy delivered for heating/cooling.

**Croatia has a total of 54 industrial companies with the total individual energy delivered for heating/cooling  $\geq 20$  GWh.**

For 2 317 out of the total of 2 478 industrial companies, the total individual energy delivered for heating/cooling is below 5 GWh.

Table I.42: INDUSTRIAL SECTOR - Total energy delivered for heating/cooling

Total individual energy delivered for heating/cooling X [GWh/a]	Number of industrial enterprises	Total energy delivered for heating/cooling [GWh/a]	Share of total energy delivered for heating/cooling [%]

### 1.2.3.5 DISTRIBUTION OF TOTAL ENERGY DELIVERED TO THE INDUSTRIAL SECTOR BY ACTIVITY

The distribution of:

- total energy delivered to the industrial sector,
- energy delivered to the industrial sector for heating,
- energy delivered to the industrial sector for cooling, and
- total energy delivered to the industrial sector for heating/cooling,

is provided in tabular form, according to the type of activity, i.e. the NCA code.

74.98% of the total energy delivered to the industrial sector for heating/cooling is used for the following activities:

1. **Manufacture of other non-metallic mineral products (50.79%),**
2. manufacture of food products (12.39%),
3. manufacture of wood and of products of wood and cork, except furniture; manufacture of articles of straw and plaiting materials (7.53%), and
4. metal production (4.50%).

Less than 3.06% of the total energy delivered for heating/cooling is consumed individually for other individual activities, stated in the table.

SEKTOR INDUSTRIJE - raspodjela ukupne isporučene energije za potrebe grijanja/hlađenja prema vrstama djelatnosti

Figure I.25: INDUSTRIAL SECTOR – Distribution of total energy delivered for heating/cooling by type of activity

CROATIAN	ENGLISH
SEKTOR INDUSTRIJE - raspodjela ukupne isporučene energije za potrebe grijanja/hlađenja prema vrstama djelatnosti	INDUSTRIAL SECTOR – Distribution of total energy delivered for heating/cooling by type of activity
Proizvodnja ostalih nemetalnih mineralnih proizvoda	Manufacture of other non-metallic mineral products
Proizvodnja prehrambenih proizvoda	Manufacture of food products
Prerada drva i proizvoda od drva i pluta, slame i pletarskih materijala	Manufacture of wood and of products of wood and cork, straw and plaiting materials
Proizvodnja metala	Metal production
Ostale djelatnosti	Other activities

Manufacture of other non-metallic mineral products (sand, gravel, stone, clay) includes: manufacture of glass and glass products, manufacture of refractory products (plaster, concrete, brick, roofing-tile), manufacture of clay products (ceramic tiles, brick, roofing-tile), manufacture of other porcelain and clay products, manufacture of cement, lime and plaster, manufacture of cement, lime and plaster products, cutting, shaping and finishing of stone, and manufacture of stone working products and non-metallic mineral products.

### 1.2.3.6 INDUSTRIAL BOILER ROOMS

**Total number of industrial boiler rooms** in Croatia in 2019: **57**

The combustion of fuel (natural gas, fuel oil, wood waste) in the industrial boiler rooms generates the following:

- steam and water at temperatures lower than or equal to 200 °C,
- steam and water temperature higher than 200 °C.

**The total consumption of energy products for the generation of steam and water** at temperatures lower than or equal to 200 °C, and steam and water at temperature higher than 200 °C in industrial boiler rooms in 2019 stood at **770.58 GWh**.

Data on the consumption of individual energy source for each industrial boiler room, as well as the data on the consumption of the generated steam/water are known. The values of actually generated steam were corrected in order to obtain the average boiler room efficiency. It is evident that natural gas (78.95%) was most frequently used for steam and water generation, followed by fuel oil (11.51%) and waste (9.53%). Seven industrial boiler rooms use exclusively waste as energy source (wood industry, manufacture of furniture).

Table I.44: shows summed up data on the consumption of individual energy sources for industrial boiler room purposes.

Table I.44: INDUSTRIAL SECTOR – Industrial boiler rooms – Total annual consumption of energy sources for steam and water generation, 2019

JLS	LSGU

The consumption of individual energy sources at the level of individual counties is shown in the table below, separately for:

- steam and water at temperatures less than or equal to 200 °C;
- steam and water at temperatures higher than 200 °C; and
- steam and water at temperatures lower than or equal to or higher than 200 °C (together).

### 1.2.3.7 INDUSTRIAL COGENERATION INSTALLATIONS

**Total number of industrial cogeneration installations** in Croatia in 2019: **5**

The industrial cogeneration installations burning exclusively fossil fuels as energy sources (natural gas, brown coal and lignite) generate:

- steam and water at temperatures lower than or equal to 200 °C; (one industrial cogeneration installation); and
- steam and water at temperatures higher than 200 °C (four industrial cogeneration installations).

Croatia's industrial companies having cogeneration installations are engaged in the following:

- manufacture of sugar (three companies, with one company using brown coal and lignite as energy sources);
- manufacture of paper and paper products (one company); and
- manufacture of chemicals and chemical products (one company).

**Total consumption of energy sources used to generate steam and water at temperatures lower than or equal to 200 °C, and steam and water at temperatures higher than 200 °C in the industrial cogeneration installations in 2019 stood at **2,013.01 GWh** .**

It is evident that natural gas (94.33%) is the most frequently used energy source for the simultaneous generation of electricity and thermal energy in industrial cogeneration installations.

A summary of data on the consumption of individual drive energy products for industrial cogeneration installation purposes is presented in Table I.49:. Data on electricity and thermal energy generated at industrial cogeneration installations, as well as the average efficiency of cogeneration installations, have also been summarised.

Table I.49: INDUSTRIAL SECTOR – Industrial cogeneration installations – Total annual consumption of drive energy products for electricity and thermal energy generation, 2019

### 1.2.3.8 DISTRIBUTION OF TOTAL ENERGY DELIVERED TO THE INDUSTRIAL SECTOR BY TECHNOLOGY

The following energy products were delivered to the industrial sector in 2019:

- steam and water,
  - supply directly from district heating systems (DHS),
  - generation from industrial boiler rooms,
  - generation at industrial cogeneration installations,
- electricity,
- natural gas, network-distributed,
- hard and brown coal and their briquettes,
- coke,
- fuel oil (extra light and special fuel oil, low-sulphur fuel oil (up to 1% S), high-sulphur fuel oil (1% S and higher; heavy oil)),
- petroleum coke,
- liquefied gas,
- biomass (firewood, wood pellets and chips, wood and straw briquettes, wood and plant waste),
- old tyres,
- waste oils and emulsions,
- meat and bone meal, and
- dried sludge – DSS.

The energy delivered to the industrial sector uses the following technologies:

- **industrial boiler rooms** for steam and water generation;
- **industrial cogeneration installations** for steam and water generation;
- **district heating system – DHS** for steam and water supply; and
- **other technologies**, which are powered by electricity, natural gas, hard and brown coal and their briquettes, coke, fuel oil, petroleum coke, liquefied gas, biomass, old tyres, waste oils and emulsions, meat and bone meal, and dried sludge – DSS.

A total of 57 industrial boiler rooms use predominantly fossil fuels and, to a lesser extent, renewable energy sources – wood waste, as energy products for steam and water generation. Consequently, a portion of steam and water generated at the industrial boiler rooms can be considered renewable energy sources.

All five industrial cogeneration installations in Croatia are powered by fossil fuels (natural gas, brown coal and lignite).

Considering that other technologies in the industrial sector depend on individual type of activity in the industrial sector, and they are unknown from the existing database, they were categorised among other technologies. There are surely industrial stoves among them, but also boilers. To be precise, natural gas, hard and brown coal and their briquettes, coke, fuel oil, petroleum coke, liquefied gas, biomass, old tyres, waste oils and emulsions, meat and bone meal, and dried sludge – DSS are unquestionably energy products that generate thermal energy by their combustion in industrial stoves and boilers. It should be noted that biomass, meat and bone meal, and dried sludge are considered to be renewable energy sources. Thus, we can differentiate between the category of other technologies powered by fossil fuels and the category of other technologies powered by renewable energy sources.

A total of 3 466.41 GWh of electricity was delivered to the industrial sector in 2019, amounting to 29.92% of the total energy delivered.

In 2019, 40.09% of consumed electricity in Croatia was generated from renewable energy sources, while 59.91% was generated from non-renewable energy sources (fossil and nuclear fuels).

Taking into consideration the shares of electricity generated from renewable and non-renewable energy sources, it follows that, for heating/cooling purposes in the industrial sector:

- 731.67 GWh of electricity was generated from non-renewable energy sources (fossil and nuclear fuels); and
- 489.67 GWh of electricity was generated from renewable energy sources (hydroelectric power plants, wind farms, solar cells, geothermal power plants).

Since technologies are unknown, electricity has also been categorised among other technologies, separating the electricity generated from non-renewable energy sources from the electricity generated from renewable energy sources.

Steam or water generated in district heating systems for the purposes of the industrial sector is generated by the following technologies:

- fossil fuel boilers (Vartop – Varaždin, Komunalac – Požega, GTG Vinkovci, Tehno stan Vukovar, Energo Rijeka, Brod Plin SB, Gradska toplana Karlovac) (75.96%);
- fossil fuel cogeneration (thermal power and heating plant Termoelektrana Toplana (TE-TO) Osijek, thermal power plant (TE) Sisak) (15.92%);
- fossil fuel high-efficiency cogeneration (electricity and heating plant Elektrana Toplana (EL-TO) Zagreb, TE-TO Zagreb) (7.33%);
- RES high-efficiency cogeneration (Sisak, Osijek) (0.76%); and
- solar collectors (Vukovar, Slavonski Brod) (0.03%).

Table I.51: INDUSTRIAL SECTOR – DHS – Distribution of DHS thermal energy delivered by generation technology

INDUSTRY – DHS	Distribution of DHS thermal energy delivered by generation technology [GWh/a]	Share [%]
DHS – fossil fuel boilers	375.85	75.96
DHS – solar collectors	0.16	0.03
DHS – high-efficiency fossil fuel cogeneration	36.25	7.33
DHS – fossil fuel cogeneration	78.79	15.92
DHS – high-efficiency RES cogeneration	3.75	0.76
<b>TOTAL</b>	<b>494.80</b>	<b>100.00</b>

Of the total steam or water energy delivered to the industrial sector from DHS, 75.96% was generated in fossil fuel boilers, 15.29% in fossil fuel cogeneration installations, and 7.33% in high-efficiency cogeneration installations.

CTS-visokučinkovita kogeneracija na OIE	DHS – high-efficiency RES cogeneration

The European Commission has prepared templates in Excel file form recommended for use, among other things, **for the printout of the energy delivered for heating/cooling purposes by analysed sectors** (households, services, industry, other sectors if undergoing comprehensive assessment). There is a distinction between:

- energy delivered on-site, and
- energy delivered off-site (DHS).

Within each analysed sector (households, services, industry, other sectors), there is also a distinction between:

- delivered energy derived from fossil fuels, and
- delivered energy derived from renewable energy sources.

A further division refers to the type of technology generating delivered energy (boilers, cogeneration, heat pumps, other technologies).

An overview of the energy delivered in the industrial sector in 2019, according to the template prepared by the European Commission, is provided in Table I.52:.

Table I.52: Overview of the energy delivered for heating/cooling purposes to the industrial sector in 2019, according to the template prepared by the European Commission

DELIVERED ENERGY PROVIDED ON-SITE			Unit	Value

### 1.2.3.9 DISTRIBUTION OF TOTAL ENERGY DELIVERED TO THE INDUSTRIAL SECTOR BY PURPOSE

Total annual energy delivered to the industrial sector for heating/cooling purposes includes the energy delivered for:

- space heating and DHW preparation,
- space cooling,
- heating in the production process, and
- cooling in the production process.

The distribution of total annual energy delivered for heating/cooling by purpose is provided in tabular form and figures. It is evident that 85.72% of the total annual energy delivered for heating/cooling is used for the purposes of heating in the production process, while 8.61% of the total annual energy delivered for heating/cooling is used for space heating and DHW preparation. Space cooling and cooling for production process purposes account for only 5.67% of the total annual energy delivered for heating/cooling.

<sup>9</sup> The figure refers to industrial boiler rooms, registered by the Croatian Bureau of Statistics and powered by fossil fuels.

<sup>10</sup> Five existing industrial cogeneration installations in Croatia powered exclusively by fossil fuels.

### 1.3 ANNUAL USEFUL ENERGY NEEDS FOR HEATING/COOLING BY SECTOR

This chapter provides the annual useful energy needed for heating/cooling in the household, service and industrial sectors, expressed in GWh.

In addition, in order to simplify reporting for the comprehensive assessment of the potential for efficient heating and cooling under Annex VIII to Directive 2012/27/EU, the European Commission has prepared and recommends the use of Excel file templates. Among other things, a **template is provided for the printout of delivered and useful energy for heating/cooling purposes by analysed sectors** (households, services, industry, other sectors if they are the subject to the comprehensive assessment).

An overview of energy delivered and useful energy needed by sectors (household, services, industry) in 2019 is provided below in tabular form (Table I.54:), following the template prepared by the European Commission.

**Total annual energy delivered for heating/cooling purposes to household, service and industrial sectors in Croatia amounted to 33 505.18 GWh in 2019.**

**Total annual useful energy needed for heating/cooling purposes to household, service and industrial sectors in Croatia amounted to 32 366.55 GWh in 2019.**

Table I.54: Overview of energy delivered and useful energy needed by sectors in 2019, according to the template prepared by the European Commission

	Sector	Unit	2019	TOTAL	
Heating demand <sup>15</sup> , <b>end-use</b> energy	HOUSEHOLDS	GWh/a	20 616.95	31 292.12	<b>33 505.18</b>

Useful energy needed for heating and cooling was derived from the energy delivered by applying specific conversion end-use factors (e.g. degrees of efficiency in heating systems and cooling factors in cooling systems).

### 1.3.1 HOUSEHOLD SECTOR

#### 1.3.1.1 TOTAL USEFUL ENERGY NEEDS FOR HEATING/COOLING

The total energy delivered to the household sector in Croatia in 2019 amounted to **26 088.45 GWh** (excluding lignite consumption and including energy taken from the environment using heat pumps).

The total energy delivered for space heating/cooling and DHW preparation to the industrial sector in Croatia in 2019 amounted to **20 927.63 GWh**. Space heating/cooling and DHW preparation (heating/cooling) accounts for 80.22% of the consumption of total energy delivered to the household sector.

Using the degrees of efficiency, that is, the coefficients of performance for heating and energy efficiency ratios for cooling provided in tabular form (Table I.58:), and depending on the energy product and technology, the **total annual useful energy needed for space heating/cooling and DHW preparation in the household sector** has been calculated at **16 647.46 GWh**.

Table I.58: HOUSEHOLD SECTOR – Degree of efficiency, i.e. coefficient of performance for heating and cooling factor

Energy product	Building type	Purpose	Degree of efficiency [-] Cooling factor [-]	
			room-based	centralised
DHS	Multi-apartment buildings	Space heating	–	0.980
		DHW preparation	–	0.980
Natural gas	Family houses	Space heating	0.700	0.850
		DHW preparation	0.750	0.800
	Multi-apartment buildings	Space heating	0.700	0.850

### 1.3.1.2 DISTRIBUTION OF TOTAL USEFUL ENERGY NEEDS FOR HEATING/COOLING BY PURPOSE

Total annual useful energy needed for space heating/cooling and DHW preparation in the household sector in Croatia amounted to **16 647.46 GWh**.

By comparing the annual energy delivered with the useful energy needed for each purpose, the following average annual degrees of efficiency of individual systems are derived:

- **heating system** → **0.752**,
- **DHW preparation system** → **0.820**,
- **space cooling system** → **2.800**.

Table I.59. HOUSEHOLD SECTOR – Overview of the annual energy delivered and useful energy needed for heating/cooling

HOUSEHOLD SECTOR	Total annual energy delivered [GWh/a]	Total annual useful energy needs [GWh/a]	Degree of efficiency [-]
Space heating	16 625.51	12 503.19	0.752
DHW preparation	3 991.44	3 274.38	0.820
Space cooling	310.68	869.89	2.800
<b>TOTAL</b>	<b>20 927.63</b>	<b>16 647.46</b>	<b>0.795</b>

Figure I.36: HOUSEHOLD SECTOR – Total annual energy delivered and useful energy needed for space heating/cooling and DHW preparation

CROATIAN	ENGLISH

PRIPREMA PTV-a	DHW PREPARATION
HLAĐENJE PROSTORA	SPACE COOLING
Isporučena energija	Delivered energy
Korisna energija	Useful energy

An analysis of the annual useful energy needs by purpose (space heating/cooling, DHW preparation) produces the following distribution of **16 647.46 GWh** in the total annual useful energy needed for space heating/cooling and DHW preparation in the household sector:

- **75.11% for space heating** (12 503.19 GWh/a),
- **19.67% for DHW preparation** (3 274.38 GWh/a),

- **5.23% for space cooling (869.89 GWh/a).**

Table I.60. HOUSEHOLD SECTOR – Total annual useful energy needs

HOUSEHOLD SECTOR	Total annual useful energy needs [GWh/a]			
	Family houses	Multi-apartment buildings	TOTAL	Share [%]
Space heating	8 563.17	3 940.02	<b>12 503.19</b>	75.11

Share [%]		75.11	19.67	5.23		100.00

The county ranking (top six) by consumption of the total annual useful energy needed for space heating/cooling and DHW preparation in the household sector, as well as useful energy needs for space heating, space cooling and DHW preparation (in the order of size from the top down) are presented in tabular form.

As expected, the City of Zagreb had the largest annual useful energy needs for space heating/cooling and DHW preparation (17.58%), followed by the Zagreb County (8.16%), the Split-Dalmatia County (7.66%), the Osijek-Baranja County (7.49%) and the Primorje-Gorski Kotar County (6.72%). The Istria County ranked 6<sup>th</sup> (4.70%).

### 1.3.1.4 SPECIFIC ANNUAL USEFUL ENERGY NEEDS FOR HEATING/COOLING BY COUNTY

Specific values of useful energy needs are provided below, according to the following purposes:

- space heating,
- DHW preparation,
- space cooling,

by counties for family houses and multi-apartment buildings separately.

#### SPECIFIC ANNUAL USEFUL ENERGY NEEDED FOR SPACE HEATING BY COUNTY

As expected, Lika-Senj County holds the highest value of specific annual useful energy needed for space heating. The lowest values are found in Dubrovnik-Neretva, Istria, Split-Dalmatia and Zadar counties.

Table I.63: HOUSEHOLD SECTOR – Family houses – Trends in specific useful energy needed for space heating by county

HOUSEHOLD SECTOR – family houses		SPACE HEATING

<b>TOTAL</b>		<b>45 449 582.03</b>	<b>3 940.02</b>	<b>86.69</b>

Table I.65: HOUSEHOLD SECTOR – Trends in specific useful energy needed for space heating

HOUSEHOLD SECTOR – DHW preparation	Useful floor area of the heated part of the building $A_K$ [m <sup>2</sup> ]	Annual useful energy needed for space heating [GWh/a]	Specific annual useful energy needed for space heating [kWh/(m <sup>2</sup> a)]
Family houses	83 481 377.45	8 563.17	102.58
Multi-apartment buildings	45 449 582.03	3 940.02	86.69
<b>TOTAL</b>	<b>128 930 959.49</b>	<b>12 503.19</b>	<b>96.98</b>

### SPECIFIC ANNUAL USEFUL ENERGY NEEDED FOR DHW PREPARATION BY COUNTY

Average specific useful energy needs for DHW preparation, reduced to the useful floor area of the heated part of the building are as follows:

- family houses – 24.78 kWh/(m<sup>2</sup>a),
- multi-apartment buildings – 26.53 kWh/(m<sup>2</sup>a).

Table I.66: HOUSEHOLD SECTOR – Trends in specific useful energy needed for DHW preparation

HOUSEHOLD SECTOR – DHW preparation	Useful floor area of the heated part of the building A <sub>k</sub> [m <sup>2</sup> ]	Annual useful energy needed for DHW preparation [GWh/a]	Specific annual useful energy needed for DHW preparation [kWh/(m <sup>2</sup> a)]
Family houses	83 481 377.45	2 068.79	24.78
Multi-apartment buildings	45 449 582.03	1 205.59	26.53
<b>TOTAL</b>	<b>128 930 959.49</b>	<b>3 274.38</b>	<b>25.40</b>

Actual values of specific annual useful energy needed for DHW preparation, derived by modelling, are significantly larger than the values presented in the *Technical regulation on energy economy and heat retention in buildings* (NN Nos 128/15, 70/18, 73/18, 86/18, and 102/20):

- 12.5 kWh/(m<sup>2</sup>a) for residential buildings with three or fewer apartments (family houses), and
- 16.0 kWh/(m<sup>2</sup>a) for residential buildings with more than three apartments (multi-apartment buildings).

### SPECIFIC ANNUAL USEFUL ENERGY NEEDS FOR SPACE COOLING BY COUNTY

Average specific useful energy needs for space cooling, reduced to the useful floor area of the heated part of the building (cooled part unknown) are as follows:

- family houses – 6.22 kWh/(m<sup>2</sup>a),
- multi-apartment buildings – 7.71 kWh/(m<sup>2</sup>a).

Table I.67: HOUSEHOLD SECTOR – Trends in specific useful energy needed for space cooling

HOUSEHOLD SECTOR – space cooling	Useful floor area of the heated part of the building A <sub>k</sub> [m <sup>2</sup> ]	Annual useful energy needed for space cooling [GWh/a]	Specific annual useful energy needed for space cooling [kWh/(m <sup>2</sup> a)]
Family houses	83 481 377.45	519.41	6.22
Multi-apartment buildings	45 449 582.03	350.48	7.71
<b>TOTAL</b>	<b>128 930 959.49</b>	<b>869.89</b>	<b>6.75</b>

The said values of the specific annual useful energy needed for space cooling in the household sector were derived by modelling of the total annual electricity for space cooling, using top-down approach, and are low due to relatively small number of space cooling appliances installed in the household sector, and not due to small cooling needs,

### 1.3.2 SERVICE SECTOR

The useful energy needs for heating, DHW preparation and cooling in the service sector have been modelled on the following:

- data on the heated area, location and building type available and determined from the IEC database; and

data on the specific energy needed for heating, DHW preparation and cooling for different types of buildings and two climate zones (continental and coastal) taken from the study entitled *Determining minimum requirements for energy performance of buildings*, prepared by the EIHP for the Ministry of Physical Planning, Construction and State Assets, 2020 [19] – (Annexes:

- Table 0.4.; Table 0.5.; Table 0.6:).

Based on such data, the energy needed for heating, DHW preparation and cooling in Croatia's service sector has been calculated at **9 095.45 GWh/a**. A more detailed presentation and distribution of energy needs are presented in the table below.

Table I.68: SERVICE SECTOR – Energy needed for heating, DHW preparation and cooling by building type

Building type	Heating [GWh/a]	DHW preparation [GWh/a]	Cooling [GWh/a]	Total [GWh/a]
Offices	823.59	61.96	728.36	1613.91
Education	459.07	74.90	519.18	1053.15
Hotels and restaurants	531.25	275.62	665.13	1472.00
Hospitals	281.47	105.33	474.72	861.52
Sports halls	206.16	31.86	54.26	292.28

Other non-residential buildings	918.397	72.75	581.76	1572.91
<b>TOTAL</b>	<b>3 958.89</b>	<b>631.86</b>	<b>4 504.70</b>	<b>9 095.45</b>
<b>SHARE</b>	<b>43.53%</b>	<b>6.95%</b>	<b>49.53%</b>	<b>100.00%</b>

#### SEKTOR USLUGA - raspodjela potrebne energije za grijanje, pripremu PTV-a i hlađenje

Figure I.43: SERVICE SECTOR – Share of energy needed for heating, DHW preparation and cooling

CROATIAN	ENGLISH
SEKTOR USLUGA – raspodjela potrebne energije za grijanje, pripremu PTV-a i hlađenje	SERVICE SECTOR – Distribution of energy needed for heating, DHW preparation and cooling
Grijanje	Heating
PTV	DHW
Hlađenje	Cooling

By comparing the annual energy delivered with the useful energy needed for each purpose, the following average annual degrees of efficiency of individual systems are derived:

- **space heating system** → **1.088**,
- **DHW preparation system** → **0.924**,
- **space cooling system** → **2.963**.

A detailed presentation of the annual energy delivered and useful energy needed is provided in the table below. It has also been shown in a graph, where the energy for heating represents the sum of energy for space heating and DHW preparation.

Table I.69: SERVICE SECTOR – Overview of the annual energy delivered and useful energy needed for heating/cooling

SERVICE SECTOR	Total annual energy delivered [GWh/a]	Total annual useful energy needs [GWh/a]	Degree of efficiency [-]
Space heating	3 639.05	3 958.89	1.088
DHW preparation	684.18	631.86	0.924
Space cooling	1 520.34	4 504.70	2.963
<b>TOTAL</b>	<b>5 843.57</b>	<b>9 095.45</b>	<b>1.556</b>

Figure I.44: SERVICE SECTOR – Total annual energy delivered and useful energy needed for space heating/cooling and DHW preparation

CROATIAN	ENGLISH
SEKTOR USLUGA- ukupna godišnja isporučena i potrebna korisna energija za potrebe grijanja/hlađenja prostora i pripremu PTV-a	SERVICE SECTOR – Total annual energy delivered and useful energy needed for space heating/cooling and DHW preparation
GRIJANJE PROSTORA	SPACE HEATING
PRIPREMA PTV-a	DHW PREPARATION
HLAĐENJE PROSTORA	SPACE COOLING
Isporučena energija	Delivered energy
Korisna energija	Useful energy

As already stated above, electricity amounts for the largest share of total energy delivered in the service sector. Since this includes direct electric resistance heating, heating using individual split / multi-split air-conditioning, heat pumps, as well as space cooling using compression cooling units, individual split/multisplit air-conditioning and VRV systems, the obtained degree of efficiency for space heating and cooling is above 1.

In addition, the energy needed for heating, DHW preparation and cooling has been analysed for each municipality, city or town, and City of Zagreb district. However, for the sake of simplicity, only county-level

data are included in the tables. The overall energy needed for heating, DHW preparation and cooling by energy product and building type is presented below, while the energy needed for each purpose (heating, DHW preparation and cooling) is provided separately in an annex to this document (Table 0.14: – Table 0.16:).

Table I.70: SERVICE SECTOR – Energy needed for heating, DHW preparation and cooling by building type at county level

### 1.3.3 INDUSTRIAL SECTOR

**Total energy delivered to the industrial sector** in Croatia amounted to **8 981.44 GWh** for a total of 2 478 companies that belong in the industrial sector according to their NCA code in 2019.

**Total energy for heating/cooling delivered to the industrial sector** in Croatia in 2019 amounted to **6 733.98 GWh**. Using the degrees of efficiency for heating and energy efficiency ratios for cooling, as defined in the tables below,

- Table I.29: INDUSTRIAL SECTOR – List of energy products taken into account
- Table I.30: INDUSTRIAL SECTOR – Use of electricity and natural gas as energy product for covering heating/cooling needs

**the total annual useful energy for heating and cooling** has been calculated at **6 623.64 GWh**.

An overview of energy delivered and useful energy needed for heating and cooling by counties in the industrial sector in 2019 is provided in Table I.72:.

It should be noted that the energy delivered and useful energy needed for heating purposes in the industrial sector include the energy for:

- heating (heating of the building space, heating for the purposes of the production process), and
- DHW preparation.

Energy delivered and useful energy needed for cooling purposes in the industrial sector, include energy for:

- cooling of the building space, and
- cooling for the purposes of the production process.

If total useful energy for heating is divided by the total energy delivered for heating at the level of entire Croatia, the average degree of efficiency of the heating and DHW preparation system is calculated at 87.32%:

$$\frac{5.546,73}{6.351,94} = 0,8732$$

If the total useful energy for cooling is divided by the total energy delivered for cooling at the level of entire Croatia, the average cooling system energy efficiency ratio is 2.82%:

$$\frac{1.076,91}{382,04} = 2,82$$

A comparison of the annual delivered and useful energy by purpose is provided in tabular form. In the case of energy use for heating purposes in the production process, the ratio between useful and delivered energy equals 86.98%. That ratio is somewhat higher when it comes to energy use for space heating and DHW preparation.

Table I.71: SERVICE SECTOR – Overview of the annual useful energy delivered and needed for heating/cooling by purpose

INDUSTRIAL SECTOR	Total annual energy delivered for heating/cooling [GWh]	Total annual energy needed for heating/cooling [GWh]	Ratio of useful energy needed and energy delivered [-]

## 2 ANNUAL ENERGY DELIVERED FOR HEATING/COOLING PURPOSES BY SECTOR AND TECHNOLOGY

### 2.1 ANNUAL ENERGY DELIVERED FOR HEATING/COOLING PURPOSES BY SECTOR AND TECHNOLOGY

In order to simplify reporting for the comprehensive assessment of the potential for efficient heating and cooling under Annex VIII to Directive 2012/27/EU, the European Commission has prepared and recommends the use of Excel file templates. Among other things, a **template is provided for the printout of the energy delivered for heating/cooling purposes by analysed sectors** (households, services, industry, other sectors if they are the subject to the comprehensive assessment). There is a distinction between:

- energy delivered on-site, and
- energy delivered off-site (referring to district heating systems).

Within each analysed sector (households, services, industry, other sectors), there is also a distinction between:

- delivered energy derived from fossil fuels, and
- delivered energy derived from renewable energy sources (RES).

A further division refers to the type of technology used for generating delivered energy (boilers, high-efficiency cogeneration, heat pumps, other technologies).

An overview of delivered energy by sectors in 2019, according to the template prepared by the European Commission, is provided in tabular form (Table I.74:) below.

**Delivered energy provided on-site** means the energy generated at the very site [at which it is used]. There is a distinction between:

- delivered energy derived from fossil fuels:
  - *boilers used for heating only* – fossil fuel boilers (natural gas, fuel oil, LPG) as sources of thermal energy in district heating systems and DHW preparation;
  - *other technologies* – individual fossil fuel furnaces as decentralised sources of thermal energy, electricity as a drive energy product generated from fossil fuels, and waste heat for DHW preparation;
  - *high-efficiency cogeneration* – not existent in the household or service sector in Croatia;
- Delivered energy derived from renewable energy sources (RES):
  - *boilers used for heating only* – biomass boilers (firewood, pellets / wood chips / briquettes) as sources of thermal energy in district heating systems and DHW preparation;
  - *RES high-efficiency cogeneration* – not existent in the household and service sector in Croatia;
  - *heat pumps* – heat taken from the environment (air, soil, water) and considered a renewable energy source has been mentioned;
  - *other technologies* – solar collectors, individual biomass furnaces (firewood, pellets / wood chips / briquettes) as decentralised sources of thermal energy, electricity as a drive energy product generated from renewable energy sources.

Compression heat pumps are categorised as renewable energy sources according to the seasonal performance factor (SPF), which is a ratio of total thermal energy delivered to the heating / DHW preparation system,  $Q_{dov}$ , and total drive electricity,  $E_{pog}$ :

$$SPF = \frac{Q_{dov}}{E_{pog}}$$

The heat pump takes heat from the environment,  $Q_{OIE}$ , (considered a renewable energy source) and, using the consumer drive electricity,  $E_{pog}$ , raises it to a higher temperature level and delivers it to the heating / DHW preparation system,  $Q_{dov}$ :

$$Q_{OIE} + E_{pog} = Q_{dov}$$

The equation for  $SPF$

$$SPF = \frac{Q_{dov}}{E_{pog}} = \frac{Q_{OIE} + E_{pog}}{E_{pog}}$$

calculates the amount of renewable energy taken from the environment,  $Q_{RES}$ :

$$Q_{OIE} = E_{pog} \cdot (SPF - 1)$$

$$Q_{OIE} = Q_{dov} \cdot \left(1 - \frac{1}{SPF}\right)$$

Renewable energy taken from the environment,  $Q_{OIE}$ , is stated under the category:

- Delivered energy derived from renewable energy sources (RES):
  - *heat pumps* – heat taken from the environment (air, soil, water) and considered a renewable energy source,  $Q_{OIE}$  [i.e.  $Q_{RES}$ ] is stated.

It is important to note that electricity is used as a drive energy product for:

- direct electric resistance space heating (individual electric heaters, electric boilers);
- space heating using compression heat pumps (individual split / multi-split A/C, VRV systems, heat pumps);
- DHW preparation (individual electric boilers);
- space cooling (individual split / multi-split A/C, VRV systems, compression coolers).

Considering that **40.09% of consumed electricity** in Croatia in 2019 **was generated from renewable energy sources** and 59.91% from non-renewable energy sources (fossil and nuclear fuels), the overall electricity delivered falls into the following two categories:

- delivered energy derived from fossil fuels:
  - *other technologies* – electricity as a drive energy product generated from fossil fuels;
- delivered energy derived from renewable energy sources (RES):
  - *other technologies* – electricity as a drive energy product generated from renewable energy sources.

Thus, the electricity delivered for space cooling using compression cooling units (decentralised or centralised) is also categorised under other technologies!

**Delivered energy provided off-site** means the energy delivered from heating systems. There is a distinction between:

- delivered energy derived from fossil fuels:
  - *waste heat* – no heating system in Croatia exploits waste heat for now;

- *high-efficiency cogeneration* – the example of DHS in Zagreb;
- *other technologies* – fossil fuel boilers, fossil fuel cogeneration;
- delivered energy derived from renewable energy sources (RES):
  - *waste heat* – no heating system in Croatia exploits waste heat for now;
  - *RES high-efficiency cogeneration* – the example of biomass BETO DHSs in Osijek and Sisak;
  - *other technologies* – RES boilers (DHS in Vukovar), solar collectors (DHS in Vukovar and Slavonski Brod), geothermal energy (DHS in Topusko).

The delivered annual energy provided off-site is allocated to its respective categories according to the shares in delivered energy provided in Table I.82., separately for each DHS.

*Technical regulation amending the Technical regulation on energy economy and heat retention in buildings* (NN No 102/2020) provides the following definition of energy delivered to a building:

- Delivered energy means the energy, expressed per energy carrier, which is conducted to the building's technical system through a system boundary in order to meet the observed needs for heating, cooling, ventilation, and air conditioning, domestic hot water and lighting according to Table 8.a.

According to the definition, energy from renewable energy sources (e.g. heat generated at the building site using solar collectors, heat taken from the environment using heat pumps) is not included in the total energy delivered to a building.

However, according to Excel file templates prepared by the European Commission, delivered energy includes all energy entering the building through a system boundary, energy from renewable sources entering through a system boundary (e.g. biomass), as well as energy from renewable energy sources generated at the building site (e.g. heat generated on-site using solar collectors, heat taken from the environment using heat pumps). Delivered energy in this study will include all the aforementioned forms of energy.

The total annual energy delivered to household, service and industrial sectors in Croatia for heating/cooling purposes in 2019 amounted to **33 505.18 GWh**.

The sectoral distribution of the annual energy delivered for heating/cooling in Croatia in 2019 is provided in tabular form. It is evident that most energy for heating/cooling purposes was delivered to the household sector (62.46%), followed by the industrial sector (20.07%) and the service sector (17.55%).

Table I.73: Total annual energy delivered for heating/cooling purposes in Croatia by sector, 2019

<b>TOTAL</b>				

It is important to point out that in Croatia, in 2019, only 6.50% of the total annual delivered energy for heating/cooling purposes is provided off-site (from district heating systems). Of the total annual delivered energy for heating/cooling purposes, 93.50% is provided on-site.

Table I.75: Total annual energy delivered for heating/cooling purposes in Croatia by sector, 2019

## 2.2 IDENTIFICATION OF THE INSTALLATIONS GENERATING WASTE HEAT OR COLD AND THEIR POTENTIAL FOR HEATING OR COOLING SUPPLY

Directive (EU) 2018/2001 on the promotion of the use of energy from renewable sources defines waste heat/cold as follows:

‘WASTE HEAT AND COLD’ means unavoidable heat or cold generated as by-product in industrial or power generation installations, or in the tertiary sector, which would be dissipated unused in air or water without access to a district heating or cooling system, where a cogeneration process has been used or will be used or where cogeneration is not feasible.

Therefore, heat or cold are considered waste only in the cases when they are by-products of another process, and would otherwise be dissipated into the environment (air, water). Waste heat is the excess heat that remains after an industrial process and heat dissipation.

Examples of waste heat:

- **computer centres or shopping centres** whose space needs to be cooled (typically, the heat dissipated for the purpose of space cooling is dissipated into the environment through a cooling unit condenser, but it would be more expedient to redirect it);
- **direct use of a cooling current on power plant condensers** (e.g. heat can be delivered for greenhouse heating).

The following categories are not considered waste heat:

- heat produced for the main purpose of being used directly on-site or off-site, which it is not a by-product of another process;
- heat from a cogeneration installation;
- heat that is used or could be used on the same site.

As part of the comprehensive assessment, it is necessary to identify the installations that are potential sources of waste heat and cold and indicate their annual potential in GWh. The following types of installations must be included as a minimum:

1. **thermal power generation installations** that can supply or can be retrofitted to supply waste heat with a total thermal capacity exceeding 50 MW;
2. **heat and power cogeneration installations** using technologies referred to in Part II of Annex I with a total thermal capacity exceeding 20 MW;
3. **waste incineration plants**;
4. **renewable energy installations** with a total thermal capacity exceeding 20 MW other than the installations, generating heating or cooling using the energy from renewable source;
5. **industrial installations** with a total thermal capacity exceeding 20 MW which can provide waste heat.

Cogeneration technologies covered by Directive 2012/27/EU on energy efficiency (EED) (Annex I, Part II):

- a) combined cycle gas turbine with heat recovery,
- b) steam back pressure turbine,
- c) steam condensing extraction turbine,
- d) gas turbine with heat recovery,
- e) internal combustion engine,
- f) microturbines,
- g) Stirling engines,

- h) fuel cells
- i) steam engines,
- j) organic Rankine cycles,
- k) any other type of technology or combination thereof falling under the definition laid down in Article 2(30) ((30) 'cogeneration' means the simultaneous generation in one process of thermal energy and electrical or mechanical energy).

### 2.2.1 THERMAL POWER GENERATION INSTALLATIONS WITH A TOTAL THERMAL CAPACITY EXCEEDING 50 MW

As part of [state-owned joint-stock power company] *Hrvatska elektroprivreda* – HEP d.d., there are three thermal power generation installations with a thermal capacity exceeding 50 MW<sub>t</sub>:

1. TE Plomin,
2. TE Rijeka and
3. KTE Jertovec.

The **Plomin Thermal Power Generation Installation (TE Plomin)** was built in the Plomin Bay and is the only active coal-fired thermal power generation installation in Croatia. The location was chosen because of a former coal mine, topographically and geologically suitable terrain, fresh and sea water supply, and a well-developed sea and land transport infrastructure. The TE Plomin is a condensing thermal power generation installation, consisting of two production units, Block A and Block B, having its own boiler and one steam turbine each. Hard coal is procured on the global market and transported by ships to the special purpose port at Plomin, where it is unloaded and delivered to an open repository by a conveyor system. Demineralised raw water from a nearby spring (Bubić Jama) is used for the production of steam, while sea water is used for cooling at both production units. The 125 MW Block A production unit was completed and put into operation in 1970. The Decision on integrated environmental protection conditions (Environmental Permit) ceased to be valid as of 1 January 2018, so Block A is a production unit unavailable until further notice. Block B production unit (TE Plomin 2) with an input of 210 MW was built and put into commercial operation in 2000. The installation was built by TE Plomin d.o.o., a joint venture 50% owned by HEP d.d. and 50% owned by RWE, Germany. As of 1 August 2017, the TE Plomin d.o.o. company was merged with HEP d.d., and operations have continued within [its generation arm] *HEP – Proizvodnja d.o.o.* Block B has been equipped with a flue gas desulphurisation installation since 2000. The device for removing nitrogen oxide from flue gases was completed and put into operation in 2017. By modernising the low-pressure part of the turbine and carrying out capital overhaul activities on other parts of the system in 2017, the internal efficiency of the turbine was improved, increasing the turbogenerator's rated power to 217 MW. Block B is connected to the electric power system by a 220/110 kV switchyard.

TE Plomin has implemented an Environmental, Quality and Energy Management System, certified in accordance with ISO 14001:2015, 9001:2015 and 50001:2018, and a Safety Management System compliant with the Decree on the prevention of major accidents involving hazardous substances.

The **Rijeka Thermal Power Generation Installation (TE Rijeka)** is located at Urinj, southeast of the city of Rijeka, on the coast, enabling the use of sea water for cooling, while the proximity of a refinery significantly facilitates energy supply. The construction of the thermal power plant began in 1974, the trial operation was during 1978, and since 1979 TPP Rijeka has been in regular production. A 320 MW condensing block was installed at the TE Rijeka, as one of the largest production facilities of *Hrvatska Elektroprivreda* at the time it was commissioned. Its advantage over standard thermal power plant blocks is the possibility of fast load regulation ranging between 25% and 100%, which makes it extremely adaptable to changes in the electric power system. TE Rijeka is connected to two 220 kV voltage transmission lines with a transmission power of 612 MW per transmission line, connected to the 380/220/110 kV Melina transformer substation. In its service life, TE Rijeka was in operation for 143 047 hours and generated 25.72 TWh of electricity or an average of 695 MWh per year with an average power of 180 MW. This means that TE Rijeka was in the so-called rotational reserve with 120 MW of power on average, that is, it was connected to the network with the

possibility of rapid power increase in the EE system if additional power was necessary due to any disruptions and, at gradients of more than 10 MW/min.

TE Rijeka has implemented an Environmental, Quality and Energy Management System, certified in accordance with ISO 14001:2015, 9001:2015 and 50001:2018, and a Safety Management System compliant with the Decree on the prevention of major accidents involving hazardous substances.

The **Jertovec Combined Cycle Power Generation Installation** (KTE Jertovec) is located in the village of Jertovec in the Konjščina municipality. Electricity generation at the power plant began in 1954, when the first (14.8 MW BBC) turbogenerator was put into operation. The second and the third (2x12.5 MW Jugoturbina-Končar) generator entered into operation in 1957. Lignite from local coal mines was used as the energy product. As the exploitation of coal mines in the Zagorje region ceased in the early 1970s due to depletion of resources, the use of coal was replaced by heavy fuel oil in reconstructed boilers. The crude oil crisis and rising prices of heavy fuel oil have made production unprofitable since 1974. At the same time, activities began on the installation of two 2x31.5 MW gas turbine generators, provided by Westinghouse as part of the construction of the Krško Nuclear Power Plant for the purpose of safety power supply. Gas turbine generators (GTG), using extra light fuel oil (ELFO) as fuel, were put into operation in 1976 and became the first gas turbine generators to be put into operation in this region. The use of natural gas as the basic fuel began by connecting the power plant to the newly built gas network in 1980. Recovery boilers were put into operation in 1980 and using the heat of the exhaust flue gases of gas turbines, they produced superheated steam, which generates an additional 10 MW of power on steam turbine generators (STG), as the first combined gas-steam blocks used for electricity generation in Croatia. **KTE Jertovec is used as a back-up electrical power plant** in Croatia's electrical power system thanks to its available power of 2x28 MW (gas turbine generators) and 2x10 MW (steam turbine generators), with the possibility of commissioning within 15 minutes of the order to do so.

KTE Jertovec has implemented an Environmental, Quality and Energy Management System, certified in accordance with ISO 14001:2015, 9001:2015 and 50001:2018, and a Safety Management System compliant with the Decree on the prevention of major accidents involving hazardous substances.

**Given the specifics of each of the three existing thermal power plants described above, it is estimated that it is unlikely that they will be used to produce waste heat or retrofitted so that they can produce waste heat.**

In particular, TE Plomin is located far from larger urban centres, so the exploitation of waste heat is technically and economically questionable. The location of TE Rijeka has already been considered several times in the context of building new production units (cogeneration, heat pumps, solar hot water collectors) in order to produce thermal energy to meet heating requirements of the city of Rijeka. In view of the distance between the city of Rijeka and the TE Rijeka site (approx. 5.5 km), the cost-effectiveness of that option has proven questionable and, taking into account the fact that the heating system in Rijeka is not integral, it can be concluded that the option is not realistic. Another option consists in building a new cogeneration installation and thermal energy marketing to the INA oil refinery. Both of these options exclude the use of the existing cogeneration block, so exploitation of waste heat of the existing TE Rijeka may be said to be unrealistic.

The KTE Jertovec site is intended for the future construction and use of modern technologies, such as battery electrolyser systems for hydrogen production. Both technologies will serve primarily for electricity system balancing and gas system decarbonisation, so the use of existing cogenerations to produce and exploit waste heat is unlikely.

### **2.2.2 COGENERATION INSTALLATIONS WITH A TOTAL THERMAL CAPACITY EXCEEDING 20 MW FOR THERMAL ENERGY AND ELECTRICITY GENERATION – HIGH-EFFICIENCY THERMAL ENERGY AND ELECTRICITY COGENERATION**

An analysis of the existing cogeneration thermal energy installations, presuming the use of high-efficiency cogeneration, has been performed.

Under the provisions of applicable statutory regulations and other relevant directives, high-efficiency cogeneration is that which through simultaneous production of electricity and thermal energy from a

cogeneration installation ensures primary energy savings (PES) of at least 10% compared with the reference values for separate production of thermal energy and electricity.

The methodology for calculating the value of primary energy savings is defined by the Rules governing the grant of eligible electricity producer status (NN Nos 132/2013, 81/14, 93/14, 24/15, 99/15 and 110/15), which also defines both technical and operational conditions for such generation installations.

In order for a generation installation to be granted the status of eligible electricity producer, it must meet the following requirements for obtaining a status decision:

- be connected to the electricity transmission or distribution grid and supply electricity to the electricity network, in accordance with the conditions of grid use;
- meet the technical and operational requirements laid down in Article 4 of the Rules governing the grant of eligible electricity producer status; and
- simultaneously produce electricity and thermal energy in a highly efficient manner and/or use waste or renewable energy sources to produce electricity in an economically appropriate manner, in accordance with environmental legislation, irrespective of the generation installation input.

The following existing thermal and electricity cogeneration installations, as part of *HEP Proizvodnja d.o.o.*, were covered by the analysis:

- [electricity and heating plant] EL-TO Zagreb;
- [thermal power and heating plant] TE-TO Zagreb;
- TE-TO Sisak,
- TE-TO Osijek.

The analysis took into account the 2019 data for these installations, based on the collected data on the annual electricity and thermal energy production, fuel consumption (types and quantities), comparing it with the reference for separate electricity and thermal energy production. Primary energy savings (PES) were calculated using the methodology defined by the Rules, and the results obtained are presented in the table below.

An extended scope of results of the high-efficiency cogeneration analysis is provided in an annex to this study (Table 0.17).

Table I.77: Results of the high-efficiency cogeneration analysis at HEP Proizvodnja d.o.o. production plants

Installation	Block name	Cogeneration unit type	Year built	Fuel 1	Fuel 2	$h_u$	PES
						%	%
EL-TO Zagreb	Block B	Steam back pressure turbine	1996 and earlier	Natural gas	Gas oil, fuel oil, LPG	94.85	0.00
	Block H	Waste heat recovery gas turbine	1996 and earlier	Natural gas	–	85.32	13.62
	Block J	Waste heat recovery gas turbine	1996 and earlier	Natural gas	–	86.55	15.41
TETO Zagreb	Block C	Extraction condensing turbine	1996 and earlier	Natural gas	Gas oil, fuel oil, LPG	0.00	0.00
	Block K	Combined cycle gas and steam turbine	2001	Natural gas	Gas oil, fuel oil, LPG	61.50	0.00
	Block L	Combined cycle gas and steam turbine	2006 and later	Natural gas	–	82.93	20.52
TETO Osijek	Block 45 MW	Extraction condensing turbine	1996 and earlier	Natural gas	Gas oil, fuel oil, LPG	65.99	0.00
	Block PTA 1	Waste heat recovery gas turbine	1996 and earlier	Natural gas	Gas oil, fuel oil, LPG	0.00	0.00
	Block PTA 2	Waste heat recovery gas turbine	1996 and earlier	Natural gas	Gas oil, fuel oil, LPG	0.00	0.00
	Block A	Extraction condensing turbine	1996 and earlier	Natural gas	Gas oil, fuel oil, LPG	0.00	0.00

Installation	Block name	Cogeneration unit type	Year built	Fuel 1	Fuel 2	h <sub>u</sub>	PES
						%	%
[Thermal power plant] TE Sisak	Block B	Extraction condensing turbine	1996 and earlier	Natural gas	Gas oil, fuel oil, LPG	0.00	0.00
	Block C	Combined cycle gas and steam turbine	2006 and later	Natural gas	–	51.26	0.00

At the time of the analysis, only Block L at TE-TO Zagreb had been granted the eligible electricity producer status. For this block, *HEP-Proizvodnja d.o.o.* signed an Addendum to the Power Purchase Agreement with the Croatian Energy Market Operator, with 27 July 2016 being defined as the first day of the eligible electricity producer status for Block L at TE-TO Zagreb. The agreement was signed for a fixed period of eight years, ten months and nine days from the date of payment of the incentive purchase price set out in the original agreement, until 5 June 2025.

Blocks H and J at EL-TO Zagreb use identical technologies. Having been implemented more recently in EL TO Zagreb, they could meet the requirements of high-efficiency cogeneration under an appropriate operating regime. Over the past calendar year, both blocks have achieved high levels of efficiency, and on the assumption of an appropriate operating regime which prevailed in 2020, they could meet the requirements of high-efficiency cogeneration. However, since neither of these blocks comply with permitted [limits for] IED emissions into air, it is realistic to expect their being turned into cold reserve and further commissioning only in the event of emergency.

On account of their electricity and heat generation performance, fuel consumption, associated technology, and non-compliance with the permitted [limits for] IED emissions into the environment, all other blocks do not realistically constitute the potential for qualifying high-efficiency cogeneration.

### 2.2.3 WASTE INCINERATION INSTALLATIONS

There are currently no waste incineration installations in Croatia.

## 2.2.4 INDUSTRIAL INSTALLATIONS THAT CAN PROVIDE WASTE HEAT

The main difficulty in estimating the sources of industrial waste heat and their real potential consists in the fact that data on waste or excess heat are not systematically recorded, either in international or national statistics. Furthermore, the potential of waste heat recovery depends significantly on the characteristics of the industrial sectors under observation, and even with the same product, it depends on fuels, conversions and process characteristics. One way of collecting data on sector characteristics and sites is to use relevant publications and contact relevant entities directly. The distribution of specified questionnaires is a useful method, but it is demanding in terms of organisation and time and the response is questionable, and so is the representativeness of the sample of industrial entities responding to the survey.

For example, industrial enterprises in different sectors were sent a request asking for characteristic data, with an overview of the processed answers provided below:

CROATIAN	ENGLISH
Provodite li iskorištavanje otpadne topline?	Do you carry out waste heat recovery?
Odgovori: DA-88%; NE-13%	Answers: YES – 88%; NO – 13%
Ukoliko DA - kategorija otpadne topline	If YES – waste heat category

Ponuđene opcije:	Offered options:
Dimni plinovi	flue gases
Rashladni medij (motora, kompresora itd.)	cooling medium (engine, compressor, etc.)
Toplina kondenzata	heat of condensate
Medij prijenosa otpadne topline	waste heat transfer medium
Ponuđene opcije:	Offered options:
Plin	gas
Voda	water
Termalno ulje	thermal oil
Temperaturne područje otpadne topline:	waste heat temperature range:
visoko (> 650°C)	high (>650 °C)
srednje (230-650°C)	medium (230–650 °C)
nisko (< 230°C)	low (<230 °C)

But as the sample of responses was too small, these results could not be considered representative for developing a model covering the wider industry.

In developed practice, there are methodologies seeking to overcome data gaps and complexity due to heterogeneous industrial sub-sectors. This is based on the knowledge of production capacities of individual entities and product groups, in conjunction with specific energy consumption. Respective potential is derived from the known load factor in the process of energy use and heat loads. An example estimating the potential according to different sources/methodologies is provided in the table below:

Table I.78: Potential of waste heat recovery in various industries

ind. sector	source/potential of waste heat recovery (%)		
	UK (McKenna et al.)	Sweden (Fjärrvärme AB)	STRATEGO (2015)
Chemical industry	7	24	25
Aluminium	20	n.a.	50
Cement industry	25	n.a.	25
Ceramics	20	n.a.	25
Manufacture of food products and beverages	7	9	25
Manufacture of glass	20	n.a.	10
Iron and steel industry	15	20	25
Base metals	n.a.	11	25
Paper and paperboard industry	7	6	n.a.
Wood industry	n.a.	18	25

Data for other sectors is also available. However, initial analyses show that the direct application of such indicators to the Croatian industry does not produce reliable results. Therefore, it is necessary to develop a more appropriate methodology based on available data on the domestic industry.

Basically, there are two axes for structuring an overview of energy use in the industry – through differentiation of the industrial sectors or production processes, and differentiation by the energy products used.

Similarly to examining the level of rational use of energy in the industry, the analysis using the energy products used first sorts electricity and energy products for heat generation. Although electricity is also used in certain processes for heat generation, waste heat generated in the process typically has no usable potential, so this energy product is omitted.

Thus, the observed heat generation energy products are the following:

- conventional fossil fuels: natural gas, extra light and special fuel oil, high-sulphur fuel oil, low-sulphur fuel oil, diesel fuels other than for transport, petrol other than for transport, liquefied gas, hard coal and its briquettes, brown coal and its briquettes, coke (metallurgical, foundry, and petroleum);
- energy transformation media (DHS, boiler rooms): steam and water at temperatures lower than or equal to 200 °C; steam and water at temperatures higher than 200 °C;

- biomass: firewood, wood pellets and chips, wood and plant waste;
- fuels from residues: waste oils and emulsions, old tyres, DSS, RDF and others.

The lower heating value of the fuel and the average degree of energy transformation were defined for each of the energy products.

In a general simplified division, space heating and cooling, DHW preparation, and heat in the production process were considered as heat utilisation methods. Space heating and cooling, as a process, was not taken into account as a relevant source of waste heat, but its potential was considered in the transformation for the medium preparation (boiler rooms etc.).

At the stated level of analysis of relevant factors and taking into account the most common energy utilisation methods, major sources of waste heat recovery in industry and their potential were considered separately in:

- transformed forms of energy – steam and hot water, separately for temperatures lower than or equal to 200 °C and higher than 200 °C;
- natural gas;
- all other fuels.

Only in the case of steam and hot water at temperatures higher than 200 °C was the waste heat generated during space heating and cooling and DHW preparation taken into account, while being considered only in the process heat generation using all other energy products. Temperature levels are such that the potential for waste heat in heating, cooling and DHW, using these other energy products, is not interesting for practical analysis.

This is presented on one axis, while industrial enterprises are grouped by sections and subsections of activities on the other axis. The following sections of the groups are of interest to the observation:

- Fabricated metal products
- Manufacture of rubber and plastic
- Chemicals and chemical products
- Motor vehicles, trailers
- Basic pharmaceutical products
- Other non-metallic minerals
- Other mining and quarrying
- Paper and paper products
- Manufacture of wood and of products of wood and cork
- Manufacture of electrical equipment
- Metal production
- Manufacture of furniture
- Manufacture of wearing apparel
- Manufacture of beverages
- Manufacture of food products
- Printing and reproduction.

According to these groups of production or energy processes, the waste heat recovery factor presumed for each group but varied again according to the energy products mentioned above. Thus, companies were processed collectively by groups but, in the second iteration, an individual factor was determined for each individual company and process where deviations pointed to the assumption being unrealistic. These presumed factors depend on the efficiency of energy transformation (boiler rooms), the efficiency of a separate thermal process, the characteristics of the process in a group, according to the energy product in each case. This indicates the total available residual heat, so its realistically recoverable share is determined according to the temperature level. The estimates made are relatively conservative. The primary energy consumed was multiplied by these factors to obtain the quantities of waste heat for each observed entity. The analysis was performed for industrial entities with the highest heat consumption, and the results of the analysis are provided at county level for easier overview in the table below.

Table I.79: Annual available waste heat and power from the industrial sector at county level

	County	Available industrial waste heat [MWh/a]	Available power of industrial waste heat [MW]
1	Zagreb County	833.92	0.39
2	Krapina-Zagorje	500.33	0.10
3	Sisak-Moslavina	35 639.89	3.97
4	Karlovac	1 983.44	0.38
5	Varaždin	5 796.30	2.03
6	Koprivnica-Križevci	4 217.49	0.81
7	Bjelovar-Bilogora	1 236.05	0.33

## 2.3 SOURCES OF GEOTHERMAL ENERGY – EXISTING AND POTENTIAL

The geothermal potential of Croatia is manifested in the form of numerous natural geothermal phenomena, mostly in the territory of the Pannonian Basin. Since baths, spas or health resorts have most often developed in these places, they have a centuries-old tradition of using geothermal water from natural springs for balneological purposes, for recreation and rehabilitation. Even though the phenomenon of spas is predominantly related to the Pannonian area (Varaždinske Toplice, Krapinske Toplice, Tuheljske Toplice, Daruvarske Toplice, Bizovačke Toplice, etc.), a few are also present in the Dinarides (Livade-Istarske Toplice, Split, Sinj, Omiš, and Mokošica near Dubrovnik).

Today, Croatia has some twenty active sites at which geothermal energy is used directly to heat water in swimming pools and for space heating, and two sites at which geothermal energy is used in agricultural greenhouse production (Table I.80:). The total capacity for direct use of geothermal energy is 83.5 MW<sub>t</sub>, of which 45.1 MW<sub>t</sub> is accounted for by space heating<sup>17</sup>.

The first geothermal power generation installation Velika 1, built in Velika Ciglena near Bjelovar, with a nominal capacity of 17.5 Mwe<sub>e</sub> has been in operation since 2018.

Calculations of the capacity and recovery of energy from geothermal water on an annual basis depend on a number of factors, such as flow-through, inlet water temperature, outlet temperature and the number of days of use during the year. Therefore, the calculations of recovered or estimated capacities may differ, depending on the circumstances of use, as well as on possible changes in the hydrodynamic characteristics of the reservoir. Given the relatively low capacity factor of the installations in use today, technical potential is several times greater than the one currently in use.

Given the increased interest in geothermal energy, a number of activities at existing sources have recently been launched to increase the use of geothermal energy. Thus, additional exploration was initiated at the Zagreb geothermal field in 2016 with the aim of maximizing the use of the existing capacities of the reservoir itself. For the time being, in addition to long-term users of the ŠRC Mladost [sports complex] and space heating of the Novi Zagreb Clinical Hospital facilities, the Faculty of Kinesiology in Zagreb has also been connected to geothermal heating, and preparations for the addition of new users are under way.

Late in 2020, the *Topusko – pametni termalni grad* (Topusko – smart thermal city) project was launched in Topusko with the aim to build new hot water network infrastructure throughout the city, connect new users, centralise management from the district heating station, connect four thermal wells into a single network, return all thermal water to the district heating station and use it for therapeutic purposes after it has been exploited for energy.

During the construction of an outdoor pool, a new high-capacity (58 °C, 10 l/s) thermal spring was discovered in Stubičke Toplice, and the possibility of its energy use is yet to be considered.

In Bošnjaci and Sv. Nedelja, where there is greenhouse production of tomatoes, the capacities of the geothermal wells used for plant heating provide the potential of expansion to exploit the remaining capacity of the spring.

A new hotel in Varaždinske Toplice was granted a concession to use geothermal water in 2019 and is expected to reopen soon. A project for the Energy renovation of a set of buildings – *Terme, Konstantinov Dom, Hidroterapija Terme and Konstantinova Kupelj* – at Trg slobode 1B and 1C in Varaždinske Toplice is also under way. It was approved under the Operational Programme “Competitiveness and Cohesion 2014–2020”, Priority Axes 4 “Promoting Energy Efficiency and Renewable Energy”, Investment Priority 4c “Supporting energy efficiency, smart energy management and renewable energy use in public infrastructure, including in public buildings and in the housing sector” and Specific Objective 4c1 “Reduction of energy consumption in public sector buildings”. The implementation of energy renovation measures for the buildings of the Special Hospital for Medical Rehabilitation (*Terme, Konstantinov dom, Hidroterapija Terme and Konstantinova Kupelj*) in Varaždinske Toplice will reduce the annual primary energy consumption by 49.79%, annual heat consumption by 51.44%, with new measures for RES use from local sources to be introduced and providing for CO<sub>2</sub> emissions to be reduced by 50.20%. Promotion and visibility activities will raise the awareness of users of the buildings of the Varaždinske Toplice Special Hospital for Medical Rehabilitation while also

informing the general public about the more efficient use of energy and daily benefits of increasing energy efficiency.

The Lipik Special Hospital for Medical Rehabilitation has a concession for geothermal water well and plans to build a replacement well, for which water rights have been granted by [the water authority] *Hrvatske Vode*, to be followed by renovation of the geothermal water installation so that it can be exploited more efficiently using its entire capacity.

### 2.3.1 EXISTING GEOTHERMAL SPRING EXPLOITATION FIELDS

Currently, there are six active geothermal projects in Croatia.

Projects in the exploitation phase:

1. Velika Ciglena – electricity generation,
2. Draškovec – electricity generation,
3. Bizovac – thermal energy generation,
4. GT Ivanić– thermal energy generation,
5. Zagreb geothermal field – thermal energy generation,
6. Bošnjaci Sjever – thermal energy generation for agricultural purposes (greenhouse production of tomatoes).

Figure I.49: Geothermal water exploitation fields

CROATIAN	ENGLISH
Geotermalno polje Zagreb	Zagreb geothermal field
Bošnjaci Sjever	Bošnjaci Sjever (North)

The first geothermal power generation installation in Croatia, Velika 1, began operating in Velika Ciglena late in 2018. The power plant operates on the principle of the Organic Rankine Cycle (ORC). Its nominal capacity is 17.5 MW, of which 10 MW is distributed to the electricity network.

A project is under way in Draškovac in the Međimurje County to build a pilot installation for an innovative advanced geothermal power generation installation with internalisation of carbon compounds. The project received a grant from the NER300 programme, the world's largest programme for financing innovative low-carbon energy demonstration projects. The unique closed technological process, which is being implemented in Draškovac for the first time in the world, includes extraction, a separation of liquid and gaseous stages, and utilisation of the geothermal resource in its liquid stage of in a binary system with real matter (e.g. ORC, Kalina), as well as the utilisation of the gaseous stage in cogeneration systems during which flue gases are collected and purified, and CO<sub>2</sub> is isolated in its entirety. The collected CO<sub>2</sub> is dissolved in the energetically recovered liquid stage of the geothermal resource; they are injected back together into the same geological layer from which they were obtained and where they are regenerated in a sustainable way.

The Bizovac geothermal field includes the Terme reservoir and the A3 + A4 reservoir. The water from this reservoir is the warmest iodine hyperthermal water in Europe<sup>18</sup>, with almost three times more salt than in sea water and with large amounts of iron, iodine and other minerals, its composition making it unique in the world. It has very favourable balneological properties, based on which Bizovačke Toplice developed into what has become a well-established spa. In addition to balneological applications, the water is also used for energy purposes by exploiting the water temperature to heat hotels and swimming pools. Water is transported by an overhead pipeline to the facilities, in which so-called plate heat exchangers are used to heat the district heating system of the Termia Hotel and sanitary water. Apart from the water, natural gas at this site – used as fuel in the hotel kitchen – is also found at the site.

Thermal mineral water was found in Ivanić Grad, and a Naftalan Special Hospital for Medical Rehabilitation was opened at the site in 1989. Water is obtained from a depth of 1 300 m, and its temperature at the wellhead is 60 °C. It has a characteristic crude oil smell and is classified as oily water. Nowadays, it is used only for special cosmetics to treat skin diseases.

Greenhouses are an example of successful commercialisation of the use of geothermal waters. For now in Croatia, geothermal water is used in greenhouse production at two locations – in Sv. Nedelja near Zagreb and in Bošnjaci near Županja. The greenhouse capacities are extensive – 3.5 ha in Bošnjaci, with the potential for expansion, and 5 ha in Sv. Nedelja – the two sites at which geothermal water is used for greenhouse heating in tomato production (Figure I.50).

### 2.3.2 GEOTHERMAL SPRING EXPLORATION AREAS

In the last few years, the Hydrocarbon Agency (AZU) has embarked on intensive preparations of the existing geological and oil-mining documentation as a basis for a tender to be called for the allocation of geothermal water exploration areas in Croatia. There are 13 currently active exploration areas in Croatia, in which new geothermal projects are expected to be developed over the next 3–5 years. In the exploration areas, the focus is on exploration activities aimed at obtaining electricity, and to a lesser extent, thermal energy generation relating mostly to local communities with plans to use thermal energy for heating the settlements.

10. Legrad-1 – electricity,
11. Ernestinovo – electricity,
12. Merhatovec – electricity,
13. Sveta Nedjelja – thermal energy.

The projects, which are currently undergoing exploration, have the potential to produce 59 MW<sub>e</sub> of electricity and can be fully implemented between 2022 and 2025.

### 2.3.3 POTENTIAL SOURCES OF GEOTHERMAL ENERGY

In addition to the previously mentioned natural sources of thermal water indicating the geothermal potential of Croatia, geothermal water was also found in many wells as part of oil and gas exploration in the second half of the 20th century. Some wells were tested during or after drilling, with a consequent confirmation of geothermal potential, but in a number of them geothermal water was only observed, with no additional testing performed to confirm there is a reservoir. It is in these numerous wells that the **huge potential for the use of geothermal resources lies**.

The total estimated potential power at 52 sites is **546 MW<sub>e</sub>** and **almost 2 000 MW<sub>t</sub>**, of which 180 MW<sub>e</sub> and 762 MW<sub>t</sub> may be expected to be exploited by 2030 and another 94 MW<sub>e</sub> and 525 MW<sub>t</sub> by 2040, with the remaining potential by 2050 (Hydrocarbon Agency, 2021). However, the final potential can be determined only after research activities have been completed.

## 2.4 REPORTED SHARE OF ENERGY FROM RENEWABLE SOURCES AND WASTE HEAT OR COLD IN THE CONSUMPTION OF DELIVERED ENERGY IN THE SECTOR OF DISTRICT HEATING SYSTEMS IN THE PAST 5 YEARS UNDER DIRECTIVE (EU) 2018/2001

There are district heating systems in a total of 16 cities in Croatia (Karlovac, Ogulin, Osijek, Požega, Rijeka, Samobor, Sisak, Slavonski Brod, Topusko, Varaždin, Velika Gorica, Vinkovci, Virovitica, Vukovar, Zagreb, Zaprešić).

In district heating systems in a total of 10 cities (Karlovac, Ogulin, Požega, Rijeka, Samobor, Varaždin, Velika Gorica, Vinkovci, Virovitica, and Zaprešić), heat is produced exclusively through fossil fuel combustion in boilers. Heating systems in Slavonski Brod and Vukovar use fossil fuel boilers to produce heat, and a smaller part of heat is derived from solar energy using built-in solar collectors.

The largest district heating system in Croatia, the one in Zagreb, produces heat through fossil fuel cogeneration and high-efficiency fossil fuel cogeneration.

District heating systems in Osijek and Sisak produce heat through fossil fuel cogeneration and high-efficiency RES cogeneration.

The Topusko heating system uses exclusively geothermal energy as a source of heat.

In order to determine the origin of thermal energy delivered from district heating systems to the household and service sectors, it is important to know the shares of individual technologies for each district heating system (see Table I.82:).

Table I.82: District heating systems in Croatia – origin of produced thermal energy delivered to household and service sectors

DISTRICT HEATING SYSTEMS – share of produced heat delivered to household and service sectors								
City	Fossil fuel boilers, [-]	RES boilers, [-]	Solar collectors, [-]	Geothermal energy, [-]	High-efficiency fossil fuel cogeneration, [-]	Fossil fuel cogeneration, [-]	High-efficiency RES cogeneration, [-]	Sum of shares [-]
1. Karlovac	1.000	–	–	–	–	–	–	1.0
2. Ogulin	1.000	–	–	–	–	–	–	1.0
3. Osijek	–	–	–	–	–	0.675	0.325	1.0
4. Požega	1.000	–	–	–	–	–	–	1.0
5. Rijeka	1.000	–	–	–	–	–	–	1.0
6. Samobor	1.000	–	–	–	–	–	–	1.0
7. Sisak	–	–	–	–	–	0.399	0.601	1.0
8. Slavonski Brod	0.997	–	0.003	–	–	–	–	1.0
9. Topusko	–	–	–	1.000	–	–	–	1.0
10. Varaždin	1.000	–	–	–	–	–	–	1.0
11. Velika Gorica	1.000	–	–	–	–	–	–	1.0
12. Vinkovci	1.000	–	–	–	–	–	–	1.0
13. Virovitica	1.000	–	–	–	–	–	–	1.0
14. Vukovar	0.952	0.033	0.015	–	–	–	–	1.0
15. Zagreb	–	–	–	–	0.338	0.662	–	1.0
16. Zaprešić	1.000	–	–	–	–	–	–	1.0

A total of 1 949.65 GWh of thermal energy was delivered in the district heating sector in Croatia in 2019. Of this, **4.9%** is accounted for by delivered energy from renewable energy sources. An overview of the share of renewable energy sources in the total delivered energy from district heating systems in the last 5 years is provided in tabular form.

Table I.83: Share of RES in the district heating sector, 2015–2019

	THERMAL ENERGY DELIVERED

### 3 MAPS OF CROATIA

Based on the analyses conducted in the two preceding chapters, this chapter includes only maps showing the following:

- distribution of annual delivered and required useful energy for heating/cooling purposes at the level of municipalities / cities or towns in the base year 2019 separately for the household sector and service sector (in the case of the City of Zagreb, the distribution is provided at the level of 17 City of Zagreb districts);
- positions of large industrial sector companies in Croatia in the base year 2019 with a total delivered energy for heating/cooling purposes exceeding 5 GWh/a (also providing an overview of the maximum heating and cooling load);
- positions of heat production facilities of the existing district heating systems in the base year 2019;
- distribution network of existing district heating systems;
- supply points of industrial installations producing waste heat;
- geothermal springs (existing and potential sources of geothermal energy).

Data presented on the maps was used to identify consumers who could be connected to a district heating system and to available sources of waste heat and renewable energy sources.

#### 3.1 MAP OF CROATIA – ANNUAL DELIVERED AND REQUIRED USEFUL ENERGY FOR HEATING/COOLING

As part of this chapter, a spatial representation of delivered and required useful energy for heating (space heating and DHW preparation) and cooling at the level of municipalities, cities or towns, and City of Zagreb districts, is provided separately for the household sector (Chapter 3.1.1) and the service sector (Chapter 3.1.2). It is based on the data already provided on delivered and required energy for those sectors. In addition, the annual energy delivered for heating/cooling purposes, as well as the maximum load for heating and cooling at industrial enterprises with a consumption exceeding 5 GWh per year, is provided in Chapter 3.1.3. As already mentioned, due to data confidentiality, no names of industrial enterprises are listed.

### 3.1.1 HOUSEHOLD SECTOR

## 3.2 MAP OF CROATIA – DISTRICT HEATING SYSTEMS

A district heating system consists of a heat generation installation and a distribution network.

### 3.2.1 GENERATION INSTALLATIONS OF EXISTING DISTRICT HEATING SYSTEMS

Generation installations of existing district heating systems are shown on the map below.

#### Lokacije toplinskih sustava u Republici Hrvatskoj

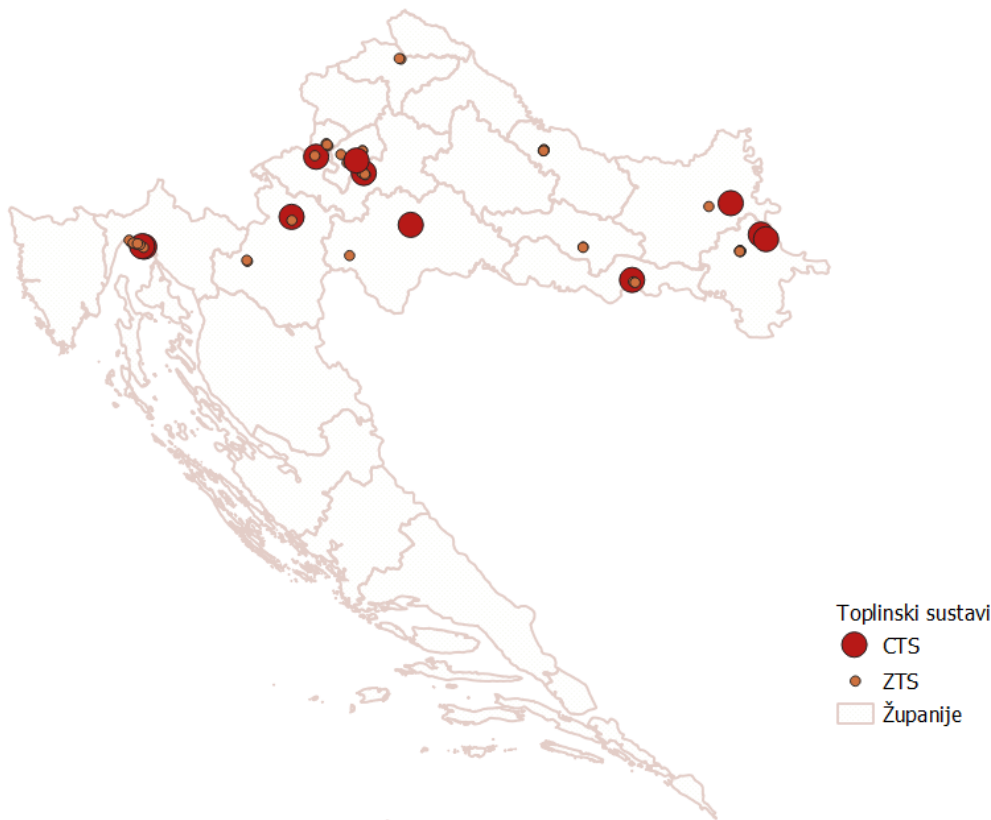

Figure I.63: Representation of heating system sites in Croatia

Toplinski sustavi	Heating systems
CTS	DHS
ZTS	CHS
Županije	Counties

### 3.2.2 GENERATION INSTALLATIONS OF PLANNED DISTRICT HEATING SYSTEMS

In the next period, a consolidation of existing closed heating systems and independent heating systems, together with neighbouring existing consumption, into district heating systems in the cities of Rijeka, Samobor and Velika Gorica.

New generation installations may also be expected at sites near the existing district heating systems in order to exploit the potential of geothermal energy in Karlovac, Vukovar, Velika Gorica, Sisak, Topusko, Zagreb, Osijek, Zaprešić, and Požega. The likelihood of construction and timeliness will depend on a number of factors with an impact on the development of the heat market, as well as on the availability of incentives for thermal energy generation from renewable energy sources.

### 3.2.3 DISTRIBUTION NETWORK OF EXISTING DISTRICT HEATING SYSTEMS

Companies managing district heating systems were asked to provide infrastructure data on individual district heating systems. Georeferenced infrastructure data in the official appropriate projection coordinate reference system of the Republic of Croatia (HTRS96/TM) in the preferred .shp or .dwg format was requested.

Table I.85: provides an overview of data provided by data format for each company and city or town.

Table I.85: Overview of the formats of provided infrastructure data on district heating systems

Company	Brod Plin	Energo	Tehnostan	HEP Toplinarstvo					Gradska Toplana
City	Slav. Brod	Rijeka	Vukovar	Zagreb	Osijek	Sisak	Samobor	Velika Gorica	Karlovac
shp	No	No	No	Yes	No	Yes	No	No	No
dwg	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes
pdf	Yes	Yes	Yes	No	No	No	No	No	No

Difficulties arising in the processing of data provided were mainly due to the following facts:

- data was not submitted in required formats;
- data was provided in required formats but included a lot of other data, making it very difficult or impossible to distinguish which data referred to the infrastructure data of district heating systems and which to other infrastructure;
- different parts of the same district heating system were provided in different formats;
- the data was not provided in the appropriate projection coordinate reference system (HTRS96/TM).

The following figures show results of the processing of infrastructure data provided, and spatial infrastructure data provided in the appropriate formats and appropriate projection coordinate reference system.

## 4 FORECAST OF DEVELOPMENTS IN ANNUAL USEFUL [ENERGY] DELIVERED AND NEEDED FOR HEATING/COOLING IN THE NEXT 10 AND 30 YEARS

Given that trends in the building stock and, consequently, the energy consumption in those buildings, are predominantly influenced by changes in population size, projections of demographic trends in Croatia are analysed first in this chapter. Next, projections of developments in the residential and non-residential building stock are analysed and presented by county for the period until 2050, along with a forecast of the developments in useful energy delivered and needed for heating and cooling. The method used to obtain these projections is described in more detail below.

### 4.1 PROJECTIONS OF DEMOGRAPHIC TRENDS

The projection of Croatia's demographic trends was taken from the analyses conducted by the Zagreb Institute of Economics [17]. The population projections were made using the cohort component method according to Rowland's methodology for an open population, by analysing three variants (detailed in the Chapter *METHODOLOGICAL APPROACH AND INPUT DATA USED IN PREPARING THE COMPREHENSIVE ANALYSIS*).

The projection of population size was made at the level of municipalities, cities or towns, and City of Zagreb districts, with Variant 2 used in all further analyses included in the Comprehensive Assessment. Therefore, the table below shows the developments in population size until 2050 only for this specific variant, with the projections provided at county level for the sake of simplicity.

Table I.86: Projection of Croatia's population size until 2030 by county – Variant 2

County name		Year						
		2021	2026	2031	2036	2041	2046	2051

## 4.2 PROJECTIONS OF TRENDS IN THE NATIONAL BUILDING STOCK

### 4.2.1 HOUSEHOLD SECTOR

Trends in the building stock are predominantly influenced by developments in population size and the expected improvement in living standards by 2050. A comparison of residential building stock data from the 2001 and the 2011 population census indicates a decline in the share of permanently occupied dwellings in the total stock, with a doubling of the floor area of temporarily and permanently vacant dwellings, and dwellings used occasionally and for other purposes. A decline in the share of permanently occupied dwellings is directly related to a decline in the number of inhabitants in the same period. Available inputs were used to model the potential condition of the residential building stock in the period until 2050. Linear regression was applied for the forecast, with a 95% probability of results falling between its upper and lower limit.

The modelling was based on trends in the total stock of permanently occupied residential buildings between 1996 and 2017. Such an approach was applied because the trend in the past eight years is not a sufficiently reliable basis for forecasting an increase in the floor area of buildings over the next 30 years. The 20-year range of inputs also includes periods of slower economic growth, return to the previous level of activity, credit expansion, recession and subsequent gradual recovery, changes in the ownership structure of the residential building stock (tenant purchase), as well as constant population outflows, thus providing a more realistic picture of long-term developments in the floor area of the building stock. Results of this analysis indicate the potential floor area of buildings to be 162 891 454 m<sup>2</sup> in 2050, ranging between 157 101 752 m<sup>2</sup> and 168 681 156 m<sup>2</sup> with a 95% probability.

Figure I.75: Forecast of trends in the floor area of Croatia's residential building stock based on the 1996–2017 data series

The ratio of the total floor area of family houses and multi-apartment buildings is maintained at 2019 levels, due to the relatively large potential deviation in the forecast of the buildings' total floor area.

The projection of an increase in the number of residential buildings and useful floor area was made under the assumption of uniform growth of the built-up building area by county, in accordance with changes in the building stock at national level between 1996 and 2017. The total floor area of residential buildings is

expected to be 138 562 785 m<sup>2</sup>, with the ratio of family houses to multi-apartment buildings remaining equal to that of today.

Table I.87: Projection of trends in Croatia's residential building stock by county until 2050

### 4.2.2 SERVICE SECTOR

Changes in the non-residential building stock are partially consistent with the trends in the residential sector, primarily due to increased economic activity; however, they are not directly comparable. Modelling of the non-residential building stock is based on analysed data from the IEC database (Chapter b.2.2 *Overview of the national building stock – service sector*). Future trends in the non-residential building stock were taken from the *Energy Development Strategy of the Republic of Croatia until 2030 with an Outlook to 2050*, according to which there will be 12 m<sup>2</sup> of non-residential buildings per capita in 2030. It is important to point out that, according to the *Rules governing energy audits and energy performance certification of buildings* (NN 88/17) [18], all public buildings exceeding 250 m<sup>2</sup> in total floor area must have an energy performance certificate. Therefore, service sector buildings with a floor area of less than 250 m<sup>2</sup> are not included in the analysis forecasting the national non-residential building stock within the Comprehensive Assessment. However, the table below also provides data from the *Long-term strategy for national building stock renovation by 2050* [20]. Based on a comparison of the data, it can be concluded that 10.6% of non-residential buildings are not in the IEC database, meaning that they have a floor area of less than 250 m<sup>2</sup> or do not possess an energy performance certificate.

Table I.88: Projection of trends in Croatia's non-residential building stock by county until 2050

## 4.3 PROJECTIONS OF DEVELOPMENTS IN USEFUL ENERGY DELIVERED AND NEEDED FOR HEATING/COOLING

Projections of the developments in the useful energy delivered and needed for heating/cooling were made for the following scenarios:

- reference or BAU (business-as-usual) scenario, which presume the development with the application of existing measures; and
- scenario with the application of additional measures according to the Integrated National Energy and Climate Plan for the Republic of Croatia (NECP) [21].

Projections of energy developments in terms of the useful energy needed and delivered energy under each scenario are presented below, including a distribution of these energy types by sector and by purpose. In addition, the distribution of the total energy delivered to household and service sectors is also presented according to energy products.

### 4.3.1 PROJECTIONS OF ENERGY DEVELOPMENTS – BAU SCENARIO

#### 4.3.1.1 DELIVERED ENERGY

The table below shows projections of the developments in the total annual energy delivered for heating/cooling purposes to household, service and industrial sectors in Croatia between 2019 and 2050 (presented graphically in Figure I.76:).

Table I.89: BAU scenario – projections of developments in total annual delivered energy by sector, 2019–2050

BAU scenario – projections of developments in the annual energy delivered for heating/cooling by sector [GWh/a]

## **DIO II. OBJECTIVES, STRATEGIES AND POLICY MEASURES**

---

## 5 CROATIA'S PLANNED CONTRIBUTION WITH ITS NATIONAL OBJECTIVES, TARGETS AND CONTRIBUTIONS TO THE FIVE DIMENSIONS OF THE ENERGY UNION

Croatia has already adopted its national objectives and targets relating to the five dimensions of the Energy Union in the Integrated National Energy and Climate Plan (NECP) for 2021–2030<sup>20</sup>, the latest version of which was adopted in December 2020. In June 2021, amendments to the NECP were prepared in order to increase the target for the share of RES in heating and cooling for 2030. Information provided below concerns the role of heating and cooling systems in achieving the objectives and targets defined in the NECP for individual dimensions.

### 5.1 DECARBONISATION

Under the decarbonisation dimension, objectives and targets are set for reducing greenhouse gas emissions and increasing RES share in gross final energy consumption by 2030.

The targets for reducing greenhouse gas emissions by 2030 are as follows:

- in the ETS sector: by at least 43% compared to the 2005 level;
- for non-ETS sectors: by at least 7% compared to the 2005 level.

As greater utilisation of RES is crucial to achieving decarbonisation targets, the following RES targets have been set for 2030:

- RES share of 39.4% in gross final energy consumption,
- RES share of 47.8% in gross final energy consumption for heating and cooling.

The indicative trajectory of increase in the share of RES for heating and cooling is shown in Figure II.1., and the share of individual technologies in Figure II.2.:

Figure II.1: Indicative trajectories of RES share in heating and cooling (Source: NECP)

<sup>20</sup> The NECP was initially adopted in December 2019, while its amendments were adopted in December 2020. The NECP version in force is available at: <https://vlada.gov.hr/sjednice/33-sjednica-vlade-republike-hrvatske-31158/31158> (accessed on 18 February 2021).

CROATIAN	ENGLISH
Udio OIE - grijanje i hlađenje	RES share – heating and cooling

Figure II.2: Share of individual RES in target gross final energy consumption (Source: NECP)

CROATIAN	ENGLISH

Energija Sunca	Solar energy
Geotermalna energija	Geothermal energy
Bruto neposredna potrošnja OIE za grijanje i hlađenje	Gross final RES consumption for heating and cooling
ktoe	ktoe

It is evident that biomass contributes most to the share of RES in gross final energy consumption, although its share in the gross final consumption of RES for heating and cooling is projected to decrease from 93.6% in 2020 to 74.8% in 2030. In 2030, the use of solar energy will have increased almost 4.5 times and the use of geothermal energy 6 times compared to 2020, with the use of heat generated from RES in district systems increasing around 4.5 times, as shown in Table II.1..

Table II.1. Estimated contribution of RES technologies in heating and cooling (Source: NECP)

ktoe	2020	2021	2022	2023	2024	2025	2026	2027	2028	2029	2030

Biomethane and hydrogen	0.0	3.2	6.4	9.6	12.8	16.0	22.4	28.7	35.1	41.5	47.9

## 5.2 ENERGY EFFICIENCY

The NECP expresses energy efficiency targets as absolute amounts of primary and final energy consumption for 2030, which must not exceed 8.23 Mtoe and 6.85 Mtoe, respectively. The NECP does not set specific targets for heating and cooling. Nevertheless, the importance of heating and cooling can be seen from the NECP determinants described below.

The structure of final energy consumption in 2030 is dominated by the building segment (households and services) at 47.43%, followed by transport at 32.29%, industry at 17.28% and agriculture at 3%. In view of the share of heating requirements in the total energy needs of a building, it is evident that measures aimed at both reducing the heating needs of buildings and the use of heating and cooling technologies of higher energy efficiency will play a major role in achieving national energy efficiency targets. It is extremely important to achieve synergy with the objectives of increasing the share of RES, that is, enable both the use of RES-based heating and cooling technologies and the electrification of heating and cooling systems, with an increase in RES share in electricity generation.

In addition, the NECP has set a target of cumulative energy savings of 2 993.7 ktoe (125.3 PJ) for 2021–2030, in accordance with Article 7 of Directive (EU) 2018/2002 amending Directive 2012/27/EU on energy efficiency. The target is not specified by sector, but it is expected to be achieved through a combination of the energy efficiency obligation scheme for energy suppliers and alternative policy measures, which include predominantly programmes for the energy renovation of buildings (more information on these programmes is provided in Chapter 6).

The importance of buildings is also clearly set out in the Long-term strategy for national building stock renovation by 2050, which was adopted in December 2020. The Long-term strategy envisages a transformation of the existing building stock into a highly energy-efficient and decarbonised building stock by 2050. The current renovation rate (2014–2019) of 0.7% of the total floor area of the building stock, or 1.35 million m<sup>2</sup> per year is foreseen to increase gradually. The target renovation rate will rise from 1% in 2021 and 2022, 1.5% in 2023 and 2024, 2.0% in 2025 and 2026, 2.5% in 2027 and 2028, and 3% in 2029 and 2030 to 3.5% between 2031 and 2040, and 4% between 2041 and 2050. The energy renovation of buildings will be predominantly based on deep energy renovation, comprising energy efficiency measures for the envelope and technical systems and reducing the annual consumption for heating ( $Q_{H,nd}$ ) and primary energy ( $E_{prim}$ ) [kWh/(m<sup>2</sup>a)] by at least 50% compared to pre-renovation energy consumption, which clearly shows the importance of buildings, as well as heating and cooling in buildings, in achieving the objectives of reducing energy consumption.

### 5.3 ENERGY SECURITY

The most important objective under the energy security dimension is to ensure a continuous, secure and high-quality supply of all energy products. Energy efficiency improvements and the use of renewable energy sources are the main mechanisms for achieving this objective, primarily by reducing the need to import fossil fuels.

According to the energy transition objective, the total energy consumption will decline by about 16% in 2050 compared to 2017. Own supply will increase to 55.2% in 2030 before decreasing to 51.7% in 2050, mostly due to the depletion of own oil and natural gas resources.

Heating is of special importance for security of supply, given the developed gas network in the continental part of Croatia and the fact that natural gas is the dominant energy product in existing district heating systems. The NECP envisages measures to enable the injection of hydrogen and biomethane into the natural gas transmission/distribution network. The transition to heating technologies using RES or heating technologies using electricity generated from RES will play an important role in reducing dependence on natural gas imports. On the other hand, it is also necessary to ensure the integration of RES into existing DHSs, as well as their further development, which is why the NECP envisages the introduction of zoning in the district heating area, as has already been done in other EU Member States.

## 5.4 INTERNAL ENERGY MARKET

The internal market dimension addresses issues of electricity interconnection, electricity and gas transmission, integration of the electricity market and energy poverty.

Electricity interconnection in Croatia is already at a high level (above the target of 15% at EU level), which is very important for the further development of the electricity market, as well as for the integration of RES. Increasing the share of RES in electricity generation is also crucial for the decarbonisation of heating and cooling systems, since it enables the electrification of such systems by using efficient technologies (e.g. heat pumps) based on electricity generated from RES.

When it comes to natural gas, the NECP recognises the importance of building new storage facilities as well as facilities for the reception, storage and regasification or decompression of liquefied natural gas (LNG) and compressed natural gas (CNG), and the integration of biomethane and hydrogen into the gas system, which is also important for the decarbonisation of heating and cooling systems.

The NECP envisages the development of a comprehensive Programme to combat energy poverty for 2021–2030, which will provide for energy consulting for all energy-poor citizens in Croatia, establish a measuring and monitoring system for indicators describing energy poverty at national level and a system to increase energy efficiency at the level of energy-poor households and households at risk of energy poverty. The comprehensive renovation of buildings of energy-poor citizens is considered a key measure for alleviating energy poverty, which will reduce the energy needs of those households (through energy efficiency measures). Their reduced energy needs, primarily in relation to heating, will be met by means of energy-efficient technologies based on RES. This will allow for a fair energy transition and ensure an accessible energy supply even for the most vulnerable groups of citizens.

## 5.5 RESEARCH, INNOVATION AND COMPETITIVENESS

This dimension of the NECP addresses the funding targets for public and private research and innovation relating to the Energy Union, objectives related to the promotion of clean and low-carbon technologies, and the improvement of national competitiveness. The NECP does not set quantitative targets related to the Energy Union in any of these areas. However, it envisages the establishment of a committee for cross-sectoral coordination of policies and measures for climate change mitigation and adaptation, whose task will be to identify national objectives and targets for this dimension, indicators needed for monitoring the achievement of the objectives and targets, and sources of data necessary for progress monitoring and evaluation.

It is expected that the research and development of new clean and low-carbon technologies, including heating and cooling technologies, will be largely funded by the Modernisation and the Innovation Fund, established following the revision of the ETS Directive. The programming of the use of European cohesion funds will be based on strategic objectives and key areas of intervention, defined in the National Development Strategy for the period until 2030. One of these strategic objectives is the green and digital transition, which will be achieved, inter alia, by a shift to clean energy and a decarbonisation of buildings, thus highlighting the significance of and the need for further development of efficient and low-carbon heating and cooling systems.

## 6 GENERAL OVERVIEW OF EXISTING POLICIES AND MEASURES

The policies and measures for achieving energy and climate objectives are defined in the NECP. An overview of key measures according to NECP dimensions, which are directly related to heating and cooling systems and have been described in detail in the NECP, is provided below.

NECP code	Title of measure
<b>MS-5</b>	CO <sub>2</sub> emissions tax for non-EU ETS stationary sources
<b>GO-5</b>	Use of biogas for biomethane production and electricity and thermal energy generation
<b>OIE-3</b>	Promoting the use of RES for electricity and thermal energy generation
<b>OIE-4</b>	Developing a regulatory framework for RES use
<b>OIE-5</b>	Promoting the use of biomethane and hydrogen from RES for thermal energy generation
<b>ENU-3</b>	Energy renovation programme for multi-apartment buildings
<b>ENU-4</b>	Energy renovation programme for family houses
<b>ENU-5</b>	Energy renovation programme for public buildings
<b>ENU-6</b>	Energy renovation programme for buildings with cultural heritage status
<b>ENU-17</b>	Increasing the efficiency of district heating systems
<b>ENU-19</b>	Increasing energy efficiency and RES use in the manufacturing industries
<b>ES-4</b>	Development and maintenance of centralised production systems
<b>UET-6</b>	Programme to combat energy poverty, including the use of RES in residential buildings in assisted areas and in areas of special state concern for 2021–2025

Of the cross-sectoral measures (MS) defined in the NECP, the most significant is the taxation of CO<sub>2</sub> emissions for non-EU ETS stationary sources. This would allow for a penalisation of heating and cooling systems using fossil fuels, focusing the transition of heating and cooling systems on the use of RES and electrification.

In the waste management sector (GO), stronger utilisation of methane generated from the anaerobic digestion of the biodegradable fraction of waste is envisaged for electricity and thermal energy generation, as well as for the injection of biomethane into the gas grid.

In the RES segment, the NECP envisages plans to develop a system of incentives for thermal energy obtained from RES while considering the possibility of co-financing construction of the necessary infrastructure, e.g. fields of solar thermal collectors, thermal energy storage facilities, installation of heat pumps. The regulatory segment envisages a further refinement of general gas supply conditions, aimed of enabling the injection of hydrogen and biomethane into the natural gas transmission/distribution network. The establishment of financial incentives for the use of biomethane and hydrogen originating from RES for heat production is also planned.

Under the energy efficiency dimension (ENU), the key measures for encouraging improved efficiency of existing heating and cooling systems, as well as their decarbonisation, are programmes for the energy renovation of buildings (multi-apartment buildings, family houses, public buildings, buildings with cultural heritage status, and buildings in areas with specific development needs and a predominantly energy-poor population). All the programmes envisage a reduction in the heating requirements of buildings by applying thermal insulation of the external envelope, as well as the replacement of thermotechnical systems, with incentives provided only for those using RES. It is precisely these programmes that are expected to contribute most to both the reduction of energy consumption in the building sector and to the decarbonisation of the heating and cooling systems used in those buildings. Energy efficiency and RES will also be encouraged in industry, which is extremely important in order to utilise the potential for the use of waste heat.

The NECP also plans to improve the DHS by reducing losses in the distribution network (measure ENU-17), as well as through its further development, which includes RES integration and the introduction of heat storage tanks in the DHS (measure ES-4).

## **DIO III. ANALYSIS OF THE ECONOMIC POTENTIAL FOR EFFICIENT HEATING AND COOLING**

---

## 7 ANALYSIS OF THE ECONOMIC POTENTIAL OF DIFFERENT HEATING AND COOLING TECHNOLOGIES

After defining and forecasting the trends in useful heat delivered and needed for heating and cooling, to analyse the economic potential of different heating and cooling technologies, it is necessary to do the following in order:

- calculate the average and maximum heating/cooling loads;
- calculate the peak load for the heat source (DHS);
- define the technical criteria necessary for heat network connection (distance limits, consumption density);
- determine the technical potential according to the baseline BAU scenario by proposing measures at the local level, as well as at the level of individual systems;
- analyse costs and benefits for each proposed measure separately.

### 7.1 CALCULATION OF AVERAGE AND MAXIMUM HEATING AND COOLING LOAD

This chapter considers three sectors (households, services and industry) and determines the following types of load for each of them:

- average heating load for heating;
- peak (maximum) heating load for heating;
- average cooling load for space cooling;
- peak (maximum) cooling load for space cooling.

These loads, which have been calculated using the formulae proposed by the European Commission in [1], are shown separately for each sector in the table below.

**NOTE:**

In household and service sectors, the term heating includes space heating and DHW preparation, while the term cooling refers to space cooling only.

In the industrial sector, the term heating includes space heating and DHW preparation, as well as heating and DHW preparation for industrial processes, while the term cooling includes space cooling and cooling for industrial processes.

The total maximum heating load for heating in household, service and industrial sectors in Croatia is 11 501.67 MW, with the total maximum cooling load for cooling purposes in those sectors standing at 1 380.17 MW.

When it comes to heating, the largest share of the total maximum heating load is accounted for by the household sector (66.87%), followed by the service sector (19.35%) and the industrial sector (13.79%).

In terms of cooling, the service sector (71.46%) has the largest share in the maximum cooling load, followed by the industrial sector (15.10%) and the household sector (13.44%).

Table III.1: Average and maximum heating/cooling load for heating/cooling by sector:

Sector name	HEATING		COOLING	
	Average heating load $Q_{AVG}$ [MW]	Maximum heating load $Q_{MAX}$ [MW]	Average cooling load $Q_{AVG}$ [MW]	Maximum cooling load $Q_{MAX}$ [MW]
HOUSEHOLDS	3 864.01	7 690.97	113.74	185.50
SERVICES	1 105.05	2 225.02	598.29	986.29
INDUSTRY	1 165.35	1 585.68	153.14	208.38
<b>TOTAL</b>	<b>6 134.42</b>	<b>11 501.67</b>	<b>865.17</b>	<b>1 380.17</b>

The distribution of the total maximum heating and cooling load for heating and cooling is provided by sector and by county. It can be observed that the highest maximum heating load for heating purposes is in the City of Zagreb (1 943.64 MW), followed by the Osijek-Baranja County (1 071.50 MW). In the case of cooling, the highest maximum cooling load can also be found in the City of Zagreb (292.51 MW), followed by the Split-Dalmatia County (209.57 MW).

## 7.2 DEFINING TECHNICAL CRITERIA NECESSARY FOR HEAT NETWORK CONNECTION

In order to assess the technical potential for heating and cooling efficiency, the following criteria have been applied:

- heat density – annual useful heating/cooling energy needs per unit area of the territory under observations;
- population density of the settlement / municipality / town or city in which the heat source (waste heat, geothermal springs) is located;
- average and maximum load of the settlement / municipality / town or city / city district in which the heat source is located;
- available amount and power of waste heat of an installation or a geothermal spring;
- distance of an area from its supply points (waste heat, geothermal energy) – observed only for the areas at a distance of less than 15 km.

## 7.3 DETERMINING THE TECHNICAL POTENTIAL

The assessment of technical potential is based purely on technical aspects with the main aim of obtaining the theoretical maximum amount of energy that could be generated through efficient heating and cooling. An economic assessment will be conducted later to determine which part of the technical potential can economically be met by the proposed efficient solutions for heating and cooling.

There is a number of solutions for efficient heating and cooling which could meet the identified useful thermal energy needs for heating and cooling. Generally speaking, a solution for heating and cooling efficiency is a combination of the following three elements:

- energy source (e.g. waste heat, biomass, electricity);
- the technology used to convert the energy source into a form of energy useful for the consumer (e.g. heat recovery, efficient boilers, heat pumps);
- distribution system delivering the useful energy to the consumer (centralised or decentralised).

Technical solutions, or measures for efficient heating and cooling proposed in the Comprehensive Assessment, are divided into measures relating to:

- decentralised (individual) systems – each consumer has their own separate source of heating and cooling energy;
- centralised systems – district heating and cooling systems distributing heat from the source to the consumer.

It is also important to mention that all the measures are based on data in the reference or BAU scenario (*Chapter: Projections of energy developments – BAU scenario*) with the tendency of achieving the energy consumption provided in the scenario with implemented measures from the Integrated National Energy and Climate Plan for the Republic of Croatia (*Chapter: Projections of energy developments – scenario with integrated measures*).

### 7.3.1 PROPOSED MEASURES FOR DISTRICT HEATING SYSTEMS

Energy efficiency measures for district heating systems include:

- increasing the efficiency and expanding the distribution network of existing district heating systems in densely populated urban areas;
- modernising the generation installations of existing district heating systems;
  - using geothermal energy sources;
  - utilisation of waste heat from industrial installations;
  - energy-from-waste;
  - using renewable energy sources (biomass, solar collectors);
  - applying biomass and natural gas high-efficiency cogeneration;
  - using a heat-carrying medium in the summer to power the central absorption chiller for cooling spaces in larger non-residential buildings (e.g. hospitals, hotels, shops, etc.) which are already connected to the district heating system (this measure has not been analysed in this Comprehensive Assessment, but it remains an option).

It is extremely important to improve the DHS, especially by reducing heat losses in the existing distribution network (NECP measure ENU-17), as well as by further developing generation installation of existing district heating systems, which implies the integration of renewable energy sources and a reduction in the use of fossil fuels.

When it comes to waste heat from existing industrial installations and the heat available from geothermal energy sources, their distance from the closest existing district heating system was taken into account first, with the use of available thermal energy within the existing district heating systems envisaged for industrial installations and geothermal sources at a distance of less than 15 km from the existing district heating systems. For installations at a distance of more than 15 km from the closest DHS, the parameters stated above underwent further analysis:

- heat density – annual useful heating/cooling energy needs per unit area of the territory under observations;
- population density of the settlement / municipality / town or city in which the heat source (waste heat, geothermal springs) is located;
- average and maximum load of the settlement / municipality / town or city / city district in which the heat source is located;
- available amount and power of waste heat of an installation or a geothermal spring.

District heating systems deliver heat to all three sectors observed (households, services, industry). The energy delivered from the DHS is not split into sectors, but rather the three analysed sectors represent one consumer.

Table III.4: shows the total annual consumption of thermal energy at the entry point to the distribution network of the district heating systems broken down by type of generation technology in:

- 2019 (reference year),
- 2030 (BAU and SIM scenarios),
- 2050 (BAU and SIM scenarios).

Table III.4: DHS – total annual energy delivered at the entry point to the distribution network of district heating systems in 2019, 2030 and 2050

Total annual energy delivered at the entry point to the distribution network of district heating systems [GWh/a]					
Name of energy product/technology	2019	BAU – 2030	BAU – 2050	SIM – 2030	SIM – 2050

DHS – industrial waste heat	0.00	0.00	0.00	15.00	22.67
DHS – thermal waste treatment heat	0.00	0.00	0.00	130.00	195.76
<b>TOTAL</b>	<b>1 823.04</b>	<b>1 884.41</b>	<b>1 822.36</b>	<b>1 723.47</b>	<b>1 542.31</b>

BAU – business-as-usual scenario, SIM – scenario with integrated measures

Figure III.1: and Figure III.2: show the development in total annual energy delivered at the entry point to the distribution network in the BAU and the SIM scenario for 2030 and 2050 according to the technologies and energy products of generation installation.

Looking at the year 2019, it can be seen that:

- 72.78% of the total delivered energy is generated in natural gas boilers;
- 10.85% of the total delivered energy is generated by natural gas cogeneration;
- 6.25% of the total delivered energy is generated from geothermal energy;
- 5.79% of the total delivered energy is generated by biomass high-efficiency cogeneration;
- only 2.11% of the total delivered energy is generated by natural gas high-efficiency cogeneration.

Therefore, boilers fired by fossil fuels (mainly natural gas, with fuel oil still used as well) are the most common type of generation installation technology in the existing district heating systems.

The BAU scenario for 2030 and 2050 forecasts a slight decrease in natural gas boilers, a complete decommissioning of fuel oil boilers by 2030, a decline in natural gas cogeneration and an increase in the use of geothermal energy, and biomass and natural gas high-efficiency cogeneration.

Figure III.1: DHS – total annual energy delivered at the entry point to the distribution network of district heating systems in 2019, 2030 and 2050 – BAU scenario

CROATIAN	ENGLISH
CTS - ukupna godišnja isporučena energija na ULAZU U DISTRIBUCIJSKU MREŽU [GWh/a] - BAU - 2019., 2030. i 2050.	DHS – total annual energy delivered at the ENTRY POINT TO THE DISTRIBUTION NETWORK [GWh/a] – BAU for 2019, 2030 and 2050
Godišnja isporučena energija na ulazu u distribucijsku mrežu [GWh/a]	Annual energy delivered at the entry point to the distribution network [GWh/a]
BAU-2030	BAU – 2030
BAU-2050	BAU – 2050
CTS-kotlovi na prirodni plin	DHS – natural gas boilers
CTS-kotlovi na biomasu	DHS – biomass boilers
CTS-biomasa-visokoučinkovita kogeneracija	DHS – biomass – high-efficiency cogeneration
CTS-geotermalna energija	DHS – geothermal energy
CTS-dizalice topline - pogonska električna	DHS – heat pumps – electrically driven
CTS-otpadna toplina iz industrije	DHS – industrial waste heat
CTS-kotlovi na loživo ulje	DHS – fuel oil boilers
CTS-prirodni plin-visokoučinkovita kogeneracija	DHS – natural gas – high-efficiency cogeneration

CTS-sunčeva energija	DHS – solar energy
CTS-dizalice topline - OIE iz okoliša	DHS – heat pumps – RES from the environment
CTS-toplina iz termičke obrade otpada	DHS – thermal waste treatment heat

The SIM scenario measures for 2030 and 2050 (Figure III.2:) foresees the following:

- complete decommissioning of fuel oil boilers (by 2030);
- complete phase-out of natural gas cogeneration;
- significant decrease in natural gas boilers;

- increase in biomass high-efficiency cogeneration;
- significant increase in geothermal energy use;
- use of heat from thermal waste treatment (significant potential in densely populated urban areas) – the figure shows electricity used as drive energy and heat taken from the environment;
- use of water-to-water compression heat pumps;
- use of industrial waste heat (small portion);
- use of solar energy (small portion).

The proposed measures would ensure a reduction in CO<sub>2</sub> emissions from district heating systems by 193 967.87 tonnes of CO<sub>2</sub> and 833.18 GWh in primary energy savings by 2030.

Between 2030 and 2050, the proposed measures would ensure a reduction in CO<sub>2</sub> emissions from district heating systems by 171 045.64 tonnes of CO<sub>2</sub> and 678.98 GWh in primary energy savings.

Today, Croatia has inefficient district heating systems, designed for high temperatures in distribution networks and an inefficient, mostly unrenovated residential building stock. The prevailing heating systems in Croatia are second-generation heating systems, which need to be upgraded to third- or fourth-generation systems. This implies new, modern generation installations, access to new sources of renewable energy, efficient distribution infrastructure, highly efficient buildings renovated for low-temperature thermal energy supply, improved control of the heating system and heat metering with charging based on the actual consumption.

Directive 2012/27/EU of the European Parliament and of the Council of 25 October 2012 **on energy efficiency** (EED) includes the following definition:

**efficient district heating and cooling** – a district heating or cooling system using at least 50% renewable energy, 50% waste heat, 75% cogenerated heat or 50% of a combination of such energy and heat.

Energy efficiency measures for district heating systems include the improvement of heat networks by renovating and reconstructing certain sections, the replacement of fuel oil boilers with heat pumps, replacement of natural gas in heat production with geothermal energy, replacement of natural gas in heat production with solar energy, replacement of old and inefficient blocks with two new high-efficiency combined-cycle cogeneration blocks, the use of waste heat from industrial installations and heat from waste incineration plants. The proposed measures are presented in more detail in the table below. The required thermal capacity of the source that needs to be installed, as well as the annual savings in delivered energy and CO<sub>2</sub> emissions after the implementation of the measures have been calculated and presented for each measure. CO<sub>2</sub> emissions savings have been calculated based on the emissions factors provided in the *Rules governing the energy savings monitoring, measuring and verification system* [22].

Table III.5. DHS – Installed capacity needed and annual primary energy and CO<sub>2</sub> emissions savings after the implementation of the proposed measures

The first measure for district heating systems is aimed at reducing heat losses in the distribution network of district heating systems. Only after that, taking into account a lower value of the delivered energy at the entry point to the distribution network due to reduced heat losses, followed the measures relating to the modernisation of generation installations of existing district heating systems:

- phase-out and complete replacement of fuel oil boilers by 2030;
- replacement of natural gas cogeneration with high-efficiency natural gas cogeneration;
- replacement of natural gas boilers (with several solutions).

#### 7.3.1.1 IMPROVEMENT OF HEAT NETWORKS THROUGH SECTION RENOVATION AND RECONSTRUCTION

As the run-down distribution network is the cause of major losses in the existing large district heating systems, this measure provides for continued replacement of hot water pipelines with deteriorated steel pipe insulation with new pre-insulated piping and a technological shift towards fourth-generation of district heating.

In good engineering practice, losses for modern heating systems using pre-insulated pipes are estimated at 6%–8%. Thanks to the resistance of pre-insulated piping material to external factors, the expected service life of the new pre-insulated pipes is up to 50 years.

The expected outcome of the heat network renovation include increased energy efficiency of the heating system, more reliable heat supply, a decrease in the number of emergency system interventions, enhanced satisfaction of the final consumers of heat, reduction of heat losses and losses in process water refilling, as well as reduced pollutant emissions into the environment.

In order for district heating systems to be sustainable by the rules of the profession and according to best practices, the existing network should be renovated to reach a level at which losses are taken to be 7% by 2030.

Total investment is estimated at around HRK 1 650 million, with support from the European Regional Development Fund through the Operational Fund for Competitiveness and Cohesion.

#### 7.3.1.2 REPLACEMENT OF FUEL OIL BOILERS BY 2030

Given that fuel oil is an environmentally unacceptable fossil fuel with a high CO<sub>2</sub> emissions factor, a complete phase-out of fuel oil as the energy product powering district heating systems is foreseen under SIM scenario measures by 2030. Two measures have been proposed: replacement of fuel oil boilers with biomass boilers (wood chips) and water-to-water heat pumps. The proposed measures should result in a reduction of CO<sub>2</sub> emissions by 9 500.95 tonnes and in 32.05 GWh in primary energy savings from drive energy products at the entry point to the DHS by 2030.

#### 7.3.1.3 REPLACEMENT OF NATURAL GAS COGENERATION WITH HIGH-EFFICIENCY NATURAL GAS COGENERATION

The proposed measures provide for the complete replacement of existing natural gas cogeneration with high-efficiency natural gas cogeneration by 2050. These measures would ensure CO<sub>2</sub> emissions savings of 29 475.79 tonnes by 2050 and 146.58 GWh in primary energy savings from drive energy products at the entry point to the DHS.

A description of the two measures for EL-TO Zagreb and TE-TO Osijek, integrated into the BAU scenario, is provided below.

### IMPLEMENTATION OF A NEW HIGH-EFFICIENCY COMBINED-CYCLE COGENERATION BLOCK AT EL-TO ZAGREB

In accordance with guidelines on energy efficiency, which form an integral part of the EU and Croatian strategic energy documents, *Hrvatska elektroprivreda* – HEP d.d. will build a new combined-cycle cogeneration block KKE EL-TO Zagreb. The block, characterised by high primary energy savings, will partially replace a portion of the deteriorated and outdated units at the EL-TO Zagreb site (block A, block B and boiler K-7).

The new high-efficiency combined-cycle cogeneration block KKE EL-TO Zagreb with an electrical capacity of 150 MW<sub>e</sub> and thermal capacity of 114 MW<sub>t</sub> will provide a reliable source of safe of electricity and heat supply to the City of Zagreb, minimising its potential interruptions.

When developing the project, HEP ensured continuous generation at the EL-TO Zagreb site to meet the needs of heat and process steam customers in the western part of the City of Zagreb even after 1 January 2018, when Croatia became subject to the provisions of EU Industrial Emissions Directive.

Since this heat-generating facility will be fuelled solely by gas, significantly lower specific CO<sub>2</sub> emissions per kWh of energy produced will be generated compared to the current situation at the site.

Table III.6: Basic information on the KKE EL-TO Zagreb project

Investor:	<i>Hrvatska elektroprivreda</i> – HEP d.d.
Location:	City of Zagreb, EL-TO Zagreb plant
Name:	KKE EL-TO Zagreb
Product type:	electricity / heat / process steam
Type of power plant:	New CCCGT block
Type of fuel:	natural gas
Capacity/efficiency:	150 MWe and 114 MW <sub>t</sub> / 90%
Annual production/regime:	675 GWh electricity, 450 GWh heat for the DHS and 160 GWh process steam for industry / base load plant
Investment value:	HRK 900 million
Funding:	Own funds / loan
Project status:	Main works on the construction of the energy-producing block began in December 2019
Length of construction:	3 years

## IMPLEMENTATION OF A NEW HIGH-EFFICIENCY COMBINED-CYCLE COGENERATION BLOCK AT TE-TO OSIJEK

*Hrvatska elektroprivreda* – HEP d.d. is developing a project to replace and expand the capacity of the existing energy installation of the thermal power and heating plant *Termoelektrana-Toplana Osijek* by constructing a new and modern combined-cycle gas-fired power plant, KKE Osijek 500, aimed at generating electricity primarily for the needs of Croatia's electricity system, as well as heat for the city of Osijek. This is a highly efficient generation facility, which will use gas as its primary fuel in a combined cycle (gas and steam turbine), with an installed electrical capacity of 450 MW<sub>e</sub> and thermal capacity of 160 MW<sub>t</sub>. Having a degree of efficiency higher than 58% and applying technical measures to achieve the highest environmental protection standards, the power plant will have low greenhouse gas emissions, especially of carbon dioxide. It will supplement the lack of generation capacities and ensure the sufficiency of heat sources in the city of Osijek, while also providing for a timely start of the process of replacing existing installations whose service life is expiring. The local community will generate an additional annual income of around HRK 15 million a year from fees for the use of space, with at least 40% of the construction to be done by domestic industry.

Table III.7: Basic information on the KKE Osijek 500 project

Investor:	<i>Hrvatska elektroprivreda</i> – HEP d.d.
Location:	City of Osijek, TE-TO Osijek plant
Name:	KKE Osijek 500
Product type:	electricity / heat / process steam
Type of power plant:	New CCCGT block
Type of fuel:	natural gas

Capacity/efficiency:	450 MWe and 160 MWt / > 58%
Investment value:	HRK 450 million
Funding:	Own funds / loan
Project status:	Project under development

### 7.3.1.4 REPLACEMENT OF NATURAL GAS BOILERS

Considering that 72.78% of the total energy delivered in 2019 was generated in natural gas boilers, making such boilers prevalent in Croatia's district heating systems, replacing them is certainly not a simple task. This Comprehensive Assessment analyses the following available technologies and potential energy sources for the replacement of natural gas boilers:

- water-to-water heat pumps;
- high-efficiency natural gas cogeneration;
- industrial waste heat utilisation;
- energy-from-waste;
- solar energy harnessing (solar collectors);
- high-efficiency biomass cogeneration (wood chips);
- biomass (wood chip) boilers;
- geothermal energy.

By 2050 the measures proposed for natural gas boilers would ensure a reduction in CO<sub>2</sub> emissions by 257 446.11 tonnes of CO<sub>2</sub> and 999.01 GWh in primary energy savings of the drive energy product at the entry point to the DHS.

#### **WATER-TO-WATER HEAT PUMPS**

Similarly to fuel oil, natural gas boilers will be partially replaced by water-to-water heat pumps. Heat pumps are not represented significantly in the technology mix of Croatia's DHS compared to other proposed replacement technologies and are primarily used in DHSs located by a river.

#### **HIGH-EFFICIENCY NATURAL GAS COGENERATION**

Since the SIM scenario does not envisage eliminating natural gas from use, but rather its reduction, it is important to use natural gas as efficiently as possible. In order to utilise the natural gas employed to its fullest potential, natural gas boilers are proposed to be replaced with high-efficiency natural gas cogeneration.

#### **INDUSTRIAL WASTE HEAT UTILISATION**

Sources of industrial waste heat constitute considerable thermal energy potential which could be utilised in district heating systems. That potential depends significantly on the characteristics of the observed industrial sectors and depends on fuels, conversions and process characteristics even in the industrial production of the same product.

The analysis of heat generated in industry has at least two dimensions – the distinction between industrial sectors or production processes, and that between the energy products used. In order to determine the amount of usable waste heat from different industrial processes, the analysis based on the energy products used first distinguishes between electricity and energy products for heat generation. Although electricity is also used in certain processes for heat generation, waste heat generated in the process typically has no usable potential, so this energy product is omitted.

Thus, the observed heat generation energy products are the following:

- conventional fossil fuels: natural gas, extra light and special fuel oil, high-sulphur fuel oil, low-sulphur fuel oil, diesel fuels other than for transport, petrol other than for transport, liquefied gas,

hard coal and its briquettes, brown coal and its briquettes, coke (metallurgical, foundry and petroleum);

- energy transformation media (DHS, boiler rooms): steam and water at temperatures lower than or equal to 200 °C; steam and water at temperatures higher than 200 °C;
- biomass: firewood, wood pellets and chips, wood and plant waste;
- fuels from residues: waste oils and emulsions, old tyres, DSS, RDF and others.

By breaking down the important factors at the given level and taking into account the most common types of energy use, the following sources are considered for their considerable potential for utilising industrial waste heat:

- transformed forms of energy – steam and hot water, separately for temperatures lower than or equal to 200 °C and higher than 200 °C;
- natural gas;
- all other fuels.

This makes it possible to derive the total available potential of residual heat and determine the realistically usable share based on the temperature level. The estimates made are relatively conservative. The analyses are conducted for industrial facilities in Croatia with the highest heat consumption.

At the current level, such an analysis points to the available annual waste heat to total 165 130 MWh/year at the installed thermal capacity of the extraction installation of 33.8 MW (economisers and other exchangers, use of waste steam, etc.).

However, due to location characteristics and temperature levels, only a small portion of those capacities can actually be utilised in district heating systems. Therefore, of the industrial installations observed, only those at a distance of less than 15 km from a potential connection to the existing (or possibly planned) DHS have been taken into account. This implies the construction of a heat transport pipeline and connection interfaces at both the source and the DHS end.

Of the total potential indicated above, the installation of 6.12 MW<sub>t</sub> in capacities for industrial heat transfer to DHSs is presumed by 2030, generating 15.31 GWh<sub>t</sub> of heat a year. Investment in the utilisation of industrial heat is presumed to continue until 2050 with the aim of achieving total capacities of 9.25 MW<sub>t</sub> for the industrial heat transfer to DHSs, generating 23.13 GWh<sub>t</sub> or heat a year.

### **INTRODUCTION OF ENERGY-FROM-WASTE**

In order to facilitate waste management, the waste in Croatia is classified according to place of origin as municipal and industrial waste and, according to its properties, as hazardous, non-hazardous or inert waste (Croatian Government, 2017).

Municipal waste refers to waste generated in the household and waste similar in nature and composition to household waste, except for production waste, and waste from agriculture and forestry<sup>21</sup>. The first step in the entire system of solid municipal waste management is to ensure the implementation of waste prevention measures defined in the *Waste management plan* (Croatian Government, 2017). The most important measures include the establishment of waste management centres (WMCs) and re-use centres, as well as the provision of equipment required for home composting. The next step consists in establishing a system for the separate collection of municipal waste by ensuring the required infrastructure for municipal waste separation: at the place of its

---

<sup>21</sup> Sustainable Waste Management Act (NN Nos 94/13, 73/17, 14/19, 98/19).

generation, at civic amenity sites, on public surfaces and through the implementation of regulations on special waste categories (SWC).

Separately collected bio-waste will be delivered to biological treatment facilities for material recovery (composting or anaerobic digestion) in order to produce compost or digestates and biogas. Mixed municipal waste (residual waste) will be collected as part of a public collection service for mixed municipal waste rendered by the service providers and delivered to WMCs directly or through transfer stations (Figure III.3:).

Sustavi za gospodarenje otpadom	Waste management systems
Izlazni materijali	Output materials

The above measures of the *Waste management plan* (Croatian Government, 2017) provide, together with the establishment of WMCs, for the use of existing and future waste management facilities, i.e. waste collection and waste treatment facilities. These include (CAEN data for 2019 and 2020<sup>23</sup>):

- civic amenity sites (a total of 173 stationary and 107 mobile sites);
- facilities for biological waste treatment (aerobic biological bio-waste treatment by composting is done at 10 composting plants);
- other facilities for material recovery of waste;
- facilities for energy recovery and waste incineration (35 energy recovery plants, with most energy recovery from waste done outside of Croatia);
- waste management centres; and
- landfills (116 landfills).

The construction of 13 WMCs is planned for the treatment of mixed municipal waste and generated waste which cannot be recycled beforehand (Figure III.4:).

It is necessary to take into account that the WMCs sites envisaged in the *Waste management plan* date from 2016, so the status of certain WMCs has changed over time. Their current status and locations are presented in tabular form (Table III.8:) and graphically (Figure III.5:).

<sup>24</sup> [https://narodne-novine.nn.hr/clanci/sluzbeni/2017\\_01\\_3\\_120.html](https://narodne-novine.nn.hr/clanci/sluzbeni/2017_01_3_120.html)

25 Waste management plan of the Republic of Croatia for 2017–2022 (NN No 3/17).

The technology envisaged for WMCs according to the *Waste management plan* is mechanical biological treatment (MBT), since it contributes to the targets for reducing the share of biodegradable waste sent to landfills and the total volume of waste landfilled. However, MBT is not enough to achieve the targets for increasing the level of municipal waste recycling. Therefore, the principle of separate waste collection from households and industry into the waste management system should be introduced, along with providing the infrastructure necessary to increase the quality of separately collected waste and preparation of waste for recycling.

Improving waste prevention measures and waste management requires action during the product life cycle, rather than in the final phase only. Factors such as the design and selection of input material play an important role in determining the service life of a product and its ability to be repaired, re-used or recycled. Despite the fact that waste recovery increases year after year, the most common type of treatment in Croatia is still the disposal of waste at landfill sites.

However, since the strategic and legislative frameworks are focused on recycling and re-use, the only waste components that can undergo energy recovery are refuse-derived fuel (hereinafter: RDF), generated in mechanical biological treatment facilities, and the separated biodegradable portion of municipal waste.

Odustalo se od izgradnje	Construction abandoned

According to European analyses, 1 million tonnes of RDF will be generated in waste management centres every year starting from 2018. However, as can be seen in Figure III.5:, most of the planned WMCs are still in the phase of project documentation preparation, resulting in the current RDF generation of around 37 000.00 tonnes at CWMC Marišćina and 11 000.00 tonnes at CWMC Kaštijun.

The generated fuel has been sold through public procurement calls for the provision of services transferring fuel from WMCs which has mostly been burnt at the existing cement plants (Holcim, Našicecement and Cemex) to date. However, considering the current capacities of the cement plants, the amounts of generated RDF envisaged will partly require the construction of 2–4 waste-to-energy plants with a treatment capacity of 150 000–400 000 tonnes of RDF per year.

Taking into account the need for additional energy in DHSs, the RDF generated in waste-to-energy plants can be utilised for the sites being considered. WMCs at those sites whose RDF would be used are the following:

- County waste management centre (CWMC) Marišćina;
- Regional waste management centre (RWMC) Orlovnjak;
- Regional waste management centre (RWMC) Šagulje;
- Waste management centre of the Karlovac County – WMC Babina Gora; and
- Waste management centre of the City of Zagreb (ZWMC).

Due to the current status of those WMCs (in respect of most of which study and project documentation preparation is still ongoing), only approximate estimates can be made of the future amounts of generated RDF to be used in waste-to-energy plants. In doing so, it is necessary to take into account that the currently estimated quantities to be treated at WMCs are going to decrease in line with bioeconomy and circular economy concepts, with more emphasis being placed on the waste prevention step. This will also lead to a significant decrease in the amount of RDF generated, which is to be used in the plants.

Given the current development and construction of WMCs, the increase in the amount of total municipal waste and in the separate collection of municipal waste (Figure III.6:), it can be concluded that RDF in WMCs will be able to significantly contribute to meeting DHS needs in the period under observation (by 2050).

Figure III.6: Quantities of separately collected municipal waste in Croatia, 2010–2019

CROATIAN	ENGLISH

In order to determine the potential for heat from thermal waste treatment that may actually be exploited in district heating systems, the above WMC sites within reach of the DHSs, i.e. less than 15 km away from a potential DHS connection, have been taken into account. The RWMC Šagulje site has been eliminated due to its remoteness to the heat network and consumers (Slavonski Brod) and excessively low capacity of networked heat consumers. The following data refer to the remaining WMC sites and the capacities derived for generating useful heat from thermal waste treatment:

Table III.9: Potential of the utilised energy from thermal waste treatment

City	WMC	Municipal waste treated at WMC [t/a]	Amount of RDF generated [t/a]	Total energy potential [GJ/a]	Electricity [GWh <sub>el</sub> /a] from cogen.	Heat from cogen. in DHS [GWh <sub>t</sub> /a]
Rijeka	CWMC Marišćina	76 896.00	37 000.00	518 000–777 000	<b>37.00</b>	<b>44</b>
Vukovar Osijek	RWMC Orlovnjak	60 000.00	28 870.16	404 180–606 270	<b>28.87</b>	<b>34</b>
Karlovac	WMC Babina Gora	29 052.00	5 688.00	91 000–125 135	<b>5.69</b>	<b>7</b>
Samobor V. Gorica Zagreb	Zagreb waste mgmt. centre (ZWMC)	180 000.00	86 610.49	1 212 545–1 818 820	<b>86.61</b>	<b>105</b>

Of the potential indicated above, the installation of capacities of 37.90 MW<sub>t</sub> for the transfer of heat to DHSs with an annual heat generation of 132.65 GWh<sub>t</sub> is presumed by 2030. Further investment in the utilisation of heat from waste treatment is assumed by 2050 with the aim of achieving a total of 57.07 MW<sub>t</sub> in capacities for the transfer of industrial heat to DHSs with an annual heat generation of 199.76 GWh<sub>t</sub>. Such heat will replace other sources of heat within DHSs.

#### **HARNESSING OF SOLAR ENERGY (solar collectors)**

This measure connects solar energy potential with the locations of the existing district heating systems by 2050. It is expected that more than 61 500 m<sup>2</sup> of thermal collectors will be installed in the heating sector by 2050, with the total investment estimated at HRK 307 million.

A greater integration of RES into district heating systems is estimated to result in a competitive price of heat in the market, which will in turn generate the need to construct new and expand existing distribution infrastructure. The harnessing of solar energy reduces the consumption of fossil fuels, which has a positive impact on the environment.

#### **HIGH-EFFICIENCY BIOMASS COGENERATION (wood chips)**

Biomass is considered a renewable energy source, so the SIM scenario provides for increased use of high-efficiency cogeneration technology using biomass (wood chips).

#### **BIOMASS (wood chip) BOILERS**

Considering a significant reduction in the use of natural gas by 2050, the SIM scenario provides for the replacement of natural gas boilers with biomass boilers.

#### **GEOHERMAL ENERGY EXPLOITATION**

This measure connects the available geothermal energy potential presented in the chapter *Sources of geothermal energy – existing and potential* with the sites of the existing district heating systems by 2050. It is estimated that the installed [capacity] in district heating systems will reach 181.73 MW<sub>t</sub> by 2050.

A greater integration of RES into district heating systems is believed to result in the supply of heat at a highly competitive prices in the market, which will in turn generate the need to build new and expand existing distribution infrastructure. Apart from geothermal heat plants, geothermal power plants or energy installations are also noteworthy, especially those of the base load type operating throughout the year with few short interruptions. In addition to electricity generation, geothermal power plant projects also enable the cascade use of the remaining geothermal water heat for different purposes (district heating, space heating, dryers, aquaculture, etc.). Such systems increase the efficiency of geothermal installations, and thus the cost-effectiveness of the entire geothermal project. Geothermal energy use reduces the consumption of fossil fuels, which has a positive impact on the environment.

## 7.3.2 PROPOSED MEASURES FOR DECENTRALISED (INDIVIDUAL) SYSTEMS

The chapter concerned includes proposes measures relating to individual systems at the level of buildings. The measures are presented separately for the household sector and the service sector, along with the achieved in delivered energy and CO<sub>2</sub> emissions savings as a result of their implementation. Moreover, the measures are also presented according to purpose: heating, DHW preparation and cooling, with the course of their implementation provided for two target years: 2030 and 2050. It is important to note that the measures below refer solely to heating, DHW preparation and cooling technologies, and that their drafting was based on data from the reference or BAU scenario, aimed at achieving the energy consumption provided in the scenario with implemented measures referred to in the Integrated National Energy and Climate Plan for the Republic of Croatia (NECP) [21].

### 7.3.2.1 HOUSEHOLD SECTOR

Energy efficiency measures for the household sector include the replacement of fossil fuels with renewable energy sources, the introduction of more efficient technologies such as condensing boilers and heat pumps, as well as the use of solar energy for heating and DHW preparation. The proposed measures are presented in more detail in the tables below. The required thermal capacity of the source that needs to be installed, as well as the annual savings in delivered energy and CO<sub>2</sub> emissions resulting from the implementation of certain measures have been calculated and presented for each measure. CO<sub>2</sub> emissions savings have been calculated based on the emissions factors provided in the *Rules governing the energy savings monitoring, measuring and verification system* [22].

Table III.10: HOUSEHOLD SECTOR – Installed capacity needed and annual primary energy and CO<sub>2</sub> emissions savings after the implementation of measures for efficient space heating

Measure code	Description of the measure	Installed thermal capacity needed [MW]		Annual primary energy savings after measure implementation [GWh]		Annual CO <sub>2</sub> emissions savings after measure implementation [tCO <sub>2</sub> ]

The implementation of the described measures will result in a significant reduction of fossil fuel consumption and, consequently, in greenhouse gas emissions too. Whenever technically feasible, fossil fuel boilers are to be replaced with renewable energy sources and more efficient technologies such as heat pumps. The percentage of individual energy product increase/decrease resulting from the implementation of these measures with regard to consumption in the reference BAU scenario for 2030 and 2050 is provided in the table below.

Table III.13: HOUSEHOLD SECTOR – Percentage of energy product increase/decrease under the BAU scenario after the implementation of measures for efficient heating, DHW preparation and cooling

Energy product	Space heating		DHW preparation		Space cooling	
	2030	2050	2030	2050	2030	2050
Traditional biomass	-8.53%	-91.00%	-20.00%	-97.00%	–	–
Modern biomass	77.09%	54.84%	75.09%	111.11%	–	–

### 7.3.2.2 SERVICE SECTOR

Similarly to the household sector, service sector energy efficiency measures include the replacement of fossil fuels with renewable energy sources, the introduction of more efficient technologies such as condensing boilers and heat pumps, as well as the use of solar energy for heating and DHW preparation. The proposed measures are presented in more detail in the tables below. The required thermal capacity of the source that needs to be installed, as well as the annual savings in delivered energy and CO<sub>2</sub> emissions resulting from the implementation of certain measures have been calculated and presented for each measure.

Table III.14: SERVICE SECTOR – Installed capacity needed and annual primary energy and CO<sub>2</sub> emissions savings resulting from the implementation of measures for efficient space heating

Measure code	Description of the measure	Installed thermal capacity needed [MW]		Annual primary energy savings after measure implementation [GWh]		Annual CO <sub>2</sub> emissions savings after measure implementation [tCO <sub>2</sub> ]	
		2030	2050	2030	2050	2030	2050
S_ELLU_1	Replacement of fuel oil boilers with modern biomass boilers	30.27	–	38.98	–	10 204.18	–

S_EE_1_a	Replacement of electric boilers with solar collectors	28.42	2.86	214.04	21.56	30 262.95	3 048.17
S_EE_2_a	Installation of heat pumps for DHW preparation	2.41	9.70	17.05	68.58	2 480.46	9 976.91

Table III.16: SERVICE SECTOR – Installed capacity needed and annual primary energy and CO<sub>2</sub> emissions savings resulting from the implementation of measures for efficient space cooling

Measure code	Description of the measure	Installed thermal capacity needed [MW]		Annual primary energy savings after measure implementation [GWh]		Annual CO <sub>2</sub> emissions savings after measure implementation [tCO <sub>2</sub> ]	
		2030	2050	2030	2050	2030	2050
S_EE_1_b	More efficient technology use (replacement of split systems with heat pumps: air-to-water, water-to-water, ground-to-water)	73.33	32.84	381.12	170.68	55 446.30	24 830.49
S_EE_2_b	Absorption cooling – connections of users to district cooling						

The implementation of the described measures will result in a significant reduction of fossil fuel consumption (complete phase-out of LPG and fuel oil in the service sector by 2050) and, consequently, in greenhouse gases emissions. Whenever technically feasible, fossil fuel boilers are to be replaced with renewable energy sources and more efficient technologies such as heat pumps. The percentage of individual energy product increase/decrease resulting from the implementation of these measures with regard to consumption in the reference BAU scenario for 2030 and 2050 is provided in the table below.

*Table III.17: SERVICE SECTOR – Percentage of energy product increase/decrease under the BAU scenario after the implementation of measures for efficient heating, DHW preparation and cooling*

Energy product	Space heating		DHW preparation		Space cooling	
	2030	2050	2030	2050	2030	2050
Modern biomass	43.59%	121.85%	75.71%	122.53%	–	–
Electricity	-20.67%	3.24%	-40.59%	-4.87%	-14.77%	-7.27%
Solar energy	82.63%	34.73%	180.31%	16.90%	–	–
LPG	-23.44%	–	-52.00%	–	–	–
Fuel oil	-73.00%	–	-98.00%	–	–	–
Natural gas	-18.31%	-59.65%	-39.55%	-72.87%	–	–
District heating	–	43.95%	–	–	–	–
Other	–	–	–	–	4.72%	15.06%

All the economic parameters which include energy product prices, CO<sub>2</sub> emissions, prices of heat sources and others are presented below.

## 8 COST-BENEFIT ANALYSIS

After the technical potential was assessed, the next logical step was to undertake a cost-benefit analysis to identify technical solutions which might be more cost-effective than all recognised heating and cooling solutions.

Croatia has completed a cost-benefit analysis: for its territory based on climate conditions, economic feasibility and technical suitability, in accordance with Annex I to Commission Delegated Regulation (EU) 2019/826 of 4 March 2019 amending Annexes VIII and IX to Directive 2012/27/EU of the European Parliament and of the Council on the contents of comprehensive assessments of the potential for efficient heating and cooling [5]. The cost-benefit analysis contributes to the easier identification of the most effective solutions for meeting heating and cooling demand, with regard to energy sources and their cost. The analysis was conducted for individual systems in the segments of households and services, and separately for DHS.

The cost-benefit analysis also took into account all relevant centralised or decentralised supply sources available within the system and geographical boundaries. To ensure that the analysis would be comprehensive, it included the following steps:

- the analysis was based on predefined technical potential (Chapter 7.3) for low-carbon and energy efficient heating and cooling;
- the baseline scenario and all relevant alternative scenarios were defined at the level of Croatia;
- financial and economic analysis was prepared, taking into account all relevant costs;
- a sensitivity analysis for all variables recognised as critical was conducted; and
- the methodology used for the calculation and defined assumptions on which the analysis is based were described in detail.

The economic and financial analyses use net present value (NPV) as a criterion for assessment. The appropriate discount rate has been applied in the calculation. Discounting enables future cash flows to be expressed in present value to determine the most cost-effective and useful heating or cooling option in Croatia and take an appropriate decision for the planning of optimal heating and cooling systems.

### 8.1.1 DEFINING SCENARIOS

This analysis compares the costs and benefits between the following two scenarios:

- reference or BAU (business-as-usual) scenario, which presumes development with the application of existing measures; and
- SIM (scenario with integrated measures) according to the Integrated National Energy and Climate Plan for the Republic of Croatia (NECP).

The baseline scenario serves as a point of reference against which alternative scenarios are assessed. It takes into account all the existing measures and policies at the time of preparing this comprehensive assessment, in accordance with national and EU law, and is based on energy efficiency and renewable energy scenarios with existing measures (WEM), developed under the provisions of the Regulation on the Governance of the Energy Union. It describes the current situation and its potential evolution if none of the parameters of the existing situation change.

Technologies envisaged under the baseline scenario do not have to be limited to the currently used options. They can also include high-efficiency cogeneration (HEC) or efficient district heating and cooling (DHC), if the baseline scenario provides for such development.

Table III.18: Energy products and technologies in the BAU scenario

Energy product	Technology	Heating	DHW	Cooling
<b>SERVICES</b>				
Fuel oil	Fuel oil boilers	x	x	
LPG	LPG boilers	x	x	
Natural gas	Natural gas boilers	x	x	
Electricity	Heat pumps	x	x	x
<b>HOUSEHOLDS</b>				
Traditional biomass	Room-based firewood stoves	x		
Traditional biomass	Firewood boilers	x	x	
Fuel oil	Fuel oil boilers	x	x	
LPG	LPG boilers	x	x	
Natural gas	Natural gas boilers	x	x	
Electricity	Electric resistance heating	x		
Electricity	Individual electric boilers		x	
Electricity	Individual compression cooling units			x

The analysis of the economic potential of different heating and cooling technologies has been conducted for the entire country through the cost-benefit analysis, identifying alternative scenarios for more efficient heating and cooling technologies using the energy from renewable sources, distinguishing between the energy derived from fossil fuels and energy derived from renewable sources. All relevant scenarios have been compared to the baseline scenario, including the role of efficient individual heating and cooling. Each scenario provides the following elements compared to those under the baseline scenario:

- economic potential of technologies examined, using the net present value as criterion;
- reducing greenhouse gas emissions;
- primary energy savings in GWh per year;
- impact on the share of renewables in the national energy mix.

Scenarios that are not feasible for technical reasons, excluding financial reasons or national regulation at an early stage of the cost-benefit analysis where justified based on careful, explicit and well-documented considerations. The assessment and decision-making have taken into account costs and energy savings from the increased flexibility in energy supply and from improved operation of the electricity networks, including avoided costs and savings resulting from reduced infrastructure investment in the analysed scenarios.

Table III.19: Overview of energy products and technologies in alternative scenarios

Type	Source	Technology	Purpose	Decentralised systems	DHS
Recovered resources	Industrial or electricity generation waste heat	Heat exchanger for industrial waste heat utilisation	Heating		√
		Heat exchanger for geothermal heat utilisation	Heating		√
RES	Geothermal energy	Solar collectors	Heating, DHW	√	√
	Biomass	Biomass boilers	Heating, DHW		√
		Modern biomass boilers	Heating, DHW	√	
		Firewood boilers	Heating	√	

Type	Source	Technology	Purpose	Decentralised systems	DHS
		Biomass high-efficiency cogeneration	Heating, DHW, electricity generation		√
	Energy from waste	Waste heat utilisation heat exchanger	Heating		√
Conventional sources	Fossil fuels	Boilers			√
		Natural gas high-efficiency cogeneration	Heating, DHW, electricity generation		√
		Natural gas micro-CHP	Heating, electricity generation	√	
	Electricity	Heat pumps	Heating, DHW, cooling	√	
		Compression heat pumps	Heating, DHW, cooling		√
		Central compression cooling unit	Cooling	√	

### 8.1.1 INPUT DATA

The first step in undertaking the analysis is the assessment of costs and benefits. They are assessed separately for the baseline scenario and the alternative scenario. Costs and benefits that remain constant in both scenarios do not have to be taken into account because they would cancel each other in the process of assessing their change between both scenarios. The same applies when implementing partial measures in the given year. A part of the baseline scenario that has not been replaced by a measure is not assessed because the same values appear in both scenarios. Also, heating and cooling consumption is the same in both scenarios, which is why it is not necessary to show these values.

Costs and benefits include:

#### BENEFITS

- value of output to the consumer (heating, cooling and electricity);
- external benefits such as environmental, greenhouse gas emissions and health and safety benefits, to the extent possible;
- labour market effects, energy security and competitiveness, to the extent possible.

#### COSTS

- capital costs of plants and equipment (CAPEX);
- capital costs of associated energy networks;
- variable and fixed operating costs (OPEX);
- energy costs;
- environmental, health and safety costs, to the extent possible.

Technical solutions, or measures for efficient heating and cooling proposed in the Comprehensive Assessment, are divided into measures relating to:

- decentralised (individual) systems – each consumer has their own separate source of heating and cooling energy;

- centralised systems (DHS) – district heating systems used for heat distribution from the source to consumers.

This division has been taken into account in the assessment of costs and benefits.

### 8.1.1.1 COST ESTIMATE

#### COSTS OF INVESTMENT OR CAPITAL EXPENDITURE (CAPEX)

Capital expenditures for heating and cooling systems include the funds necessary for the implementation of an individual technology. In the context of heating and cooling, certain equipment will differ from case to case: equipment for heat generation/recycling, pumps (in individual systems), pipelines for heat transfer in centralised systems, boilers and the like.

The cost of investment into measures related to decentralised (individual) systems have been taken from the database used for the draft Analysis of energy efficiency measures specifying unit prices and total prices of the renovation of multi-apartment buildings and public buildings and the study entitled Determining minimum requirements for energy performance of buildings. The cost of investment into measures related to centralised systems have been estimated by experience and based on the data received from heat producers/suppliers. Both have been shown in Table III.20.:

Table III.20: Overview of specific costs of investment by technology (CAPEX)

Technology	Cost of investment [HRK/kW]***
<b>Investment for decentralised (individual) systems</b>	
Fuel oil boilers	995.000
LPG boilers	995.000
Natural gas boilers	1 045.000
Firewood boilers	1 146.000
Modern biomass boilers	1 075.000
Heat pumps	4 413.000
Solar collectors***	5 000.000
Natural gas micro-CHP	5 520.000
<b>Investment for centralised systems</b>	
Fuel oil boilers	760.870
Natural gas boilers	760.870
Natural gas cogeneration	6 300.000
Biomass boilers	760.87
High-efficiency natural gas cogeneration	8 000.00
Water-to-water compression heat pump	3 971.700
Geothermal plant with plate and pipe heat exchanger for geothermal heat exploitation	20 625.000
Solar collectors***	5 000.000
CHP EL-TO Zagreb – measure integrated into BAU scenario	7 894.737
CHP EL-TO Osijek – measure integrated into BAU scenario	2 812.500
Industrial waste heat plants	14 500.000
Waste incinerators	11 500.000

\*\*\*The price of solar collectors is expressed in HRK/m<sup>2</sup>.

BAU scenario provides for the regular replacement of the currently used heat generation equipment, since service lives of certain capacities are to end during the observation period. Replacement rate has been determined based on the expected service life of technologies, which is 20 years in most cases. Thus, a 5% annual replacement rate has been used, except in the cases in which it has been assumed

that replacement of the entire capacity is necessary, where the total replacement has been linearly distributed over the observation period.

#### *Construction period*

Time required for plant construction should be specified in order to distribute the cost over the time required to complete the construction of an individual system. In order to simplify the analysis, a one-year period is assumed as the construction period for all individual system technologies. In the case of DHS, a longer period has been foreseen for the renovation of the existing plants, so the replacement costs have been distributed over more years, depending on the technology used.

### **MANAGEMENT AND MAINTENANCE COSTS (OPEX)**

Operational costs refer to the consumption of material, maintenance, administration, cost of labour etc. They can be fixed or variable.

**Fixed costs** of maintenance and management (OPEX) include labour, insurance, regular maintenance and routine replacement of plant components, such as boilers, carburettors, raw material handling equipment, etc. Replacement parts and additional servicing costs constitute the greatest share of **variable costs** of management and maintenance. These can also include other costs, such as the cost of biomass ash management. In this analysis, due to their nature and limited data availability, the variable costs of management and maintenance for individual systems have been estimated jointly with the fixed costs. In the case of DHS, fixed and variable costs of management and maintenance have been considered separately. Under the alternative scenario, the share of OPEX in CAPEX technologies ranges between 0.14% (solar collectors) and 23.44% (modern biomass boilers). In the case of DHS, this share is significantly lower, primarily due to the economies of scale, so it ranges between 0.14% (solar collectors) and 3.68% (biomass boilers).

Fixed costs of management and maintenance are calculated by multiplying the installed capacity of the observed technology by fixed costs of individual technology expressed in [HRK/kW].

In the case of DHS, variable costs of maintenance are calculated by multiplying the annual energy consumption of the drive energy product for the observed technology by variable costs of individual technology expressed in [HRK/kW].

In the case of DHS, variable costs of maintenance are calculated by multiplying the annual energy consumption of the drive energy product for the observed technology by variable costs of individual technology expressed in [HRK/kW].

The specific values of fixed and variable costs of maintenance applied for individual technology in decentralised (individual) and centralised systems are provided in Table III.21.:

*Table III.21: Overview of maintenance costs of individual technologies (OPEX)*

System type	Name of technology	Fixed maintenance costs [HRK/kW]	Variable maintenance costs [HRK/kWh]
	Room-based firewood stoves	50.00	–
	Firewood boilers	100.00	–
	Natural gas condensing boilers	120.00	–
	Natural gas boilers	120.00	–
	LPG boilers	120.00	–
Decentralised system	Fuel oil boilers	180.000	–
	Modern biomass boilers	252.000	–
	Heat pumps	120.000	–
	Electric resistance heating	1.000	–
	Individual electric boilers	1.000	–
	Individual compression cooling units	100.000	–

System type	Name of technology	Fixed maintenance costs [HRK/kW]	Variable maintenance costs [HRK/kWh]
	Central compression cooling unit	120.000	–
	Solar collectors	10.000 <sup>26</sup>	–
	Natural gas micro-CHP	240.000	–
	Heating substation within the building	2.000	–
Central systems	Solar collectors	10.000 <sup>Error!</sup> Bookmark not defined.	0.000
	Water-to-water compression heat pump	29.800	0.0010
	Heat exchanger for industrial waste heat utilisation	55.000	0.1000
	Waste heat utilisation heat exchanger	55.000	0.1000
	Heat exchanger for geothermal heat utilisation	55.000	0.1000
	Fuel oil boilers	25.000	0.0034
	Natural gas boilers	22.350	0.0030
	Natural gas and fuel oil blocks	25.000	0.0030
	Natural gas and gas oil blocks	25.000	0.0030
	Natural gas cogeneration	45.000	0.0400
	High-efficiency natural gas cogeneration	40.000	0.0370
	High-efficiency, biomass cogeneration	50.000	0.0500
	DHS pipeline distribution – HRK/m	52.150 <sup>27</sup>	0.0000

## COSTS OF ENERGY PRODUCTS AND CO<sub>2</sub> EMISSIONS

Costs of energy products are determined separately. The total amount is derived by multiplying total energy consumption, expressed in MW, with the relative price of a specific energy product, multiplied by 1 000.

The prices of energy products and CO<sub>2</sub> emissions that have been used can be found in Table III.22. The table shows a lower and a higher price<sup>28</sup>.

### *Sources of energy products prices and CO<sub>2</sub> emission prices*

Unit prices of drive energy products in 2019 have been taken to be average market values, excluding fees and VAT. Price projections for drive energy products (natural gas, electricity, crude petroleum distillates) for 2030 and 2050 are based on data reported in the Green Paper [16], while unit price trends for woody biomass (firewood, wood pellets / wood chips / briquettes) for the period up to 2050 have been estimated by experience.

The unit price of electricity in 2019, excluding levies and VAT, has been taken from the EUROSTAT website:

- household sector  
[https://ec.europa.eu/eurostat/databrowser/view/nrg\\_pc\\_204/default/table?lang=en](https://ec.europa.eu/eurostat/databrowser/view/nrg_pc_204/default/table?lang=en)
- service sector

<sup>26</sup> [HRK/m<sup>2</sup>]

<sup>27</sup> [HRK/m]

<sup>28</sup> The effect of applying a higher price will be examined in the sensitivity analysis.

[https://ec.europa.eu/eurostat/databrowser/view/nrg\\_pc\\_205/default/table?lang=en](https://ec.europa.eu/eurostat/databrowser/view/nrg_pc_205/default/table?lang=en)

The price of CO<sub>2</sub> emissions has been taken from the European Commission. The data have been corrected, taking into account the actual price trends.

Given that the chosen methodology of assessing the cost-effectiveness of each measure (net present value) requires data for costs and benefits for each year of the period under observation, and based on the known values of unit prices of energy products and CO<sub>2</sub> emissions in 2019, 2030 and 2050, linear interpolation was applied to determine unit prices in the remaining years of the period covered by the analysis, between 2020 and 2050.

Table III.22: Unit prices of energy and CO<sub>2</sub> emission in 2019, 2030 and 2050

Unit prices of energy and CO <sub>2</sub> emissions		2019		2030				2050

### Calculation of annual greenhouse gas emissions

Formula for the calculation of annual greenhouse gas emissions:

$$E_{CO_2} = FES \times e / 1000$$

Where:

$E_{CO_2}$  [t CO<sub>2</sub>/yr] – greenhouse gas emission;

FES [kWh/yr] – total annual final energy savings;

e [kg CO<sub>2</sub> / kWh] emissions factor, depending on the energy product.

The following are provided in tabular form:

- primary energy factors (source *Methodology of energy audits of buildings 2021*) and
- CO<sub>2</sub> emissions factors [tonne of CO<sub>2</sub>/GWh] (source *Draft revision of the Rules for monitoring, measuring and verifying energy savings*, ANNEX B, Table 5).

Table III.23: Primary energy factors and CO<sub>2</sub> emissions factors

Energy product	Primary energy factor [–]	CO <sub>2</sub> emissions factor [t CO <sub>2</sub> /GWh] [kg CO <sub>2</sub> /MWh]
Traditional biomass (firewood)	1.000	29.09
Modern biomass (wood pellets / wood chips)	0.139	38.38
Electricity	1.614	234.81
District heating	1.494	362.49
Solar energy	0.000	7.04
LPG	1.160	260.88
Fuel oil	1.138	299.57
Natural gas	1.095	220.20
Geothermal energy	0.000	23.48
Hydrogen	–	–
Biomethane	–	–

Modern biomass refers to wood pellets and wood chips. Given that these energy products have somewhat different factor values according to the *Methodology of energy audits of buildings 2021*, modern biomass has been calculated as the average factor value for wood pellets and wood chips.

#### 8.1.1.2 ASSESSMENT OF BENEFITS

In this analysis, the following main benefits of the implementation of the proposed measures have been recognised:

##### a. Differential cost of energy used for heating or cooling

Energy product costs are usually lower in alternative scenarios compared to BAU scenario. Only the measures envisaging the use of more expensive energy products compared to the ones used in BAU scenario (e.g. biomass over firewood or electricity over firewood) actually generate higher energy product costs for consumers. Such measures are recommended to be implemented if economically feasible due to greater reduction in CO<sub>2</sub> emissions. Their implementation usually requires some form of government incentives.

##### b. Revenues from sale of electricity (only in HEC)

Electricity generation in the use of high-efficiency cogeneration for thermal energy production provides revenues from the sale of electricity.

### c. Residual value

This is the residual value of technology, which represents its market value or liquidation value if it is sold off at the end of the year under observation. For certain technologies whose service life (usually 20 years) will not have ended by then the residual value at the end of the observation period (years 2030 and 2050) has been estimated. That value was added to total income under alternative and BAU scenarios. A positive difference between the residual values in an alternative scenario and BAU scenario represents income and contributes to a higher NPV of measure implementation. The opposite is true as well.

### d. Difference in CO<sub>2</sub> emissions

In the economic analysis, positive difference in CO<sub>2</sub> emissions between an alternative scenario and BAU scenario represents additional value for society. The amount of CO<sub>2</sub> emission reduction is expressed in tonnes [t CO<sub>2</sub>/a] and monetised by multiplying it with the appropriate emission price.

In addition, the government may provide incentives or subsidies for certain technologies. No such cases are included in this analysis.

## 8.1.2 ANALYSIS PROCEDURE

The present value of expected cash flows is calculated for the entire assessment period by discounting annual cash flows, which represent differential cost and benefits of the implementation of a certain measure in respect of the current situation. The following formula is used in the calculation:

$$S_0 = \sum_{t=1}^T \frac{V_t}{(1+k)^t}$$

Where:

- S<sub>0</sub> – net present value;
- T – total assessment period;
- V<sub>t</sub> – cash flow in year t;
- k – discount factor (opportunity cost).

The net present value of a measure compared to the situation with no change (baseline scenario or BAU scenario) is calculated by adding up discounted differences in benefits and cost differential in a single year within the observation period. According to the net present value criterion, the higher the net present value, the more cost-effective the measure is.

The analysis is conducted separately for the measures to be taken by 2030 and those referring to the period between 2031 and 2050. The analysis assumes that the measures referring to the period up to 2030 are to be implemented in phases during the 11-year period from 2020 to 2030. The measures are to be introduced in phases, at the same intensity over those 11 years, that is, with 1/11 of total expected costs of investment under the alternative scenario in each year. The measures defined for the period up to 2050 are to be implemented in phases, starting from 2031 until 2050. The measures are envisaged to be introduced in phases, at the same intensity over those 20 years, that is, with 1/20 of total costs of investment envisaged in each year.

The residual value at the end of the assessment period, separately for 2030 and 2050, has been forecast both under baseline and alternative scenarios, depending on the expected replacement rate under the baseline scenario, or the pace of new technology introduction under the alternative scenario.

NPV is calculated separately for each measure, in respect of the part of the baseline scenario to which the measure applies. Then, the NPV of a measure is divided by the total number of replaced energy product units under the baseline scenario in order to calculate the NPV by unit of energy [HRK/MWh].

### Financial and economic analysis

Cost-benefit analysis includes financial analysis from the point of view of the investor, as well as economic analysis which also considers socioeconomic and environmental factors and includes costs of CO<sub>2</sub> emissions. In calculating NPV, the financial analysis applies the financial discount rate, representing opportunity cost for the consumer, while the economic analysis applies the economic discount rate to assess the justification of the project for society as a whole. A measure is financially justified if the financial NPV is above zero. Otherwise, the measure is not cost-effective for the consumer. If a measure has a negative financial NPV and a positive economic NPV, subsidies for the implementation of the measure or some other form of support is proposed because the implementation of such a measure is considered desirable for society as a whole.

The economic analysis serves to support the adoption of appropriate policies. The benefit of conducting the analysis from both perspectives consists in identifying potential areas in which appropriate policies should be implemented, considering the gap between the cost-effectiveness of the measure and its benefit from the point of view of society. Based on that gap, actions to support or promote the measure or the cancellation of the existing or planned support mechanisms, if the assessment proves it not to be justified society-wise, are proposed.

**Discount rate** used in the economic analysis to calculate the net present value is chosen according to European or national guidelines. A 2% financial discount rate and a 5% social discount rate are applied in this analysis. In the absence of national guidelines, the discount rate values used are similar to those used by other EU Member States in their analyses.

By applying an appropriate discount rate, future costs and benefits can be expressed in the corresponding present value to render them comparable over time.

### Changes in relative prices

The analysis is conducted using constant prices defined in the base year, given that a real discount rate is applied. When a significant change in the prices of some input variables or products is expected, either above or below the average inflation rate, that difference should be taken into account in respective cash flow projections. In this analysis, this primarily applies to price trends of energy products, including electricity. The prices of energy product have thus been corrected by the expected 2% inflation rate in the observed period.

### 8.1.3 RESULTS OF COST-BENEFIT ANALYSIS

The analysis was conducted separately for the 2020-2030 period in respect of the measures foreseen up to 2030, and additionally for the 2021-2050 period in respect of the measures foreseen up to 2050. In the case of individual systems, measures for households and services have been analysed separately. DHS measures refer to all sectors under observation in this study (household sector, service sector, industrial sector) taken together. Results of the cost-benefit analysis are provided below.

#### 8.1.3.1 INDIVIDUAL SYSTEMS

The results of financial and economic analysis for households and services are provided below.

A total of 15 heating measures, 16 DHW measure and one cooling measure were analysed for households. Alternatives to traditional biomass, fuel oil, LPG, natural gas and electricity have been proposed for heating and cooling, New alternatives are modern biomass and solar energy. The use of traditional biomass, natural gas and electricity is to be maintained by applying a more efficient technology. Fuel oil should be dropped from use, with LPG use reduced by 2030. In cooling, the use of centralised instead of individual cooling units is recommended.

Figure III.7: and Figure III.8: show investment (CAPEX) and maintenance costs (OPEX) and the costs of drive energy products for all technologies of individual household and service sector systems sector for two scenarios (BAU or baseline scenario, and SIM or alternative scenario) and the two periods under observation (up to 2030, and 2030–2050).

Figure III.7: HOUSEHOLD SECTOR – 2030 and 2050 cost distribution, in HRK mil.

CROATIAN	ENGLISH
Ishodišni scenarij	Baseline scenario
Alternativni scenarij	Alternative scenario
Troškovi ulaganja (CAPEX)	Investment costs (CAPEX)
Troškovi održavanja (OPEX)	Maintenance costs (OPEX)
Trošak energenta	Cost of energy product

Figure III.8: SERVICE SECTOR – 2030 and 2050 cost distribution, in HRK mil.

CROATIAN	ENGLISH
Ishodišni scenarij	Baseline scenario
Alternativni scenarij	Alternative scenario
Troškovi ulaganja (CAPEX)	Investment costs (CAPEX)
Troškovi održavanja (OPEX)	Maintenance costs (OPEX)
Trošak energenta	Cost of energy product

The costs of drive energy products are lower in SIM or alternative scenarios than in BAU scenarios, which is among the main benefits of the implementation of measures.

The results of completed financial and economic cost-benefit analysis for proposed household sector measures in the period up to 2030 and between 2031 and 2050 are presented in Table III.24:.

The results of completed financial and economic cost-benefit analysis for proposed service sector measures in the period up to 2030 and between 2031 and 2050 are presented in Table III.25:.

Table III.24: HOUSEHOLD SECTOR – results of completed financial and economic cost-benefit analysis up to 2030, and in 2031–2050

## HOUSEHOLD SECTOR – Analysis of the results of cost-benefit analysis

Firewood is largely in use in households as drive energy product either in individual room stoves or in central firewood boilers.

Based on the cost-benefit analysis, the **measure of replacing individual firewood stoves** with central firewood boilers up to 2030 proved not to be cost-effective (FNPV > 0 and ENPV > 0).

Furthermore, the **measure involving the replacement of central firewood boilers** with central modern biomass boilers for space heating and DHW preparation also proved not to be cost-effective (FNPV > 0 and ENPV > 0) given that the cost of modern biomass is higher than the cost of firewood. Moreover, modern biomass has a somewhat higher CO<sub>2</sub> emissions factor than firewood.

The measure involving central firewood boiler replacement with heat pumps also proved not to be cost-effective (FNPV > 0 and ENPV > 0).

Under the proposed measures in the household sector, **a complete cessation of fuel oil use** as a drive energy product for space heating and DHW preparation is foreseen by 2030. The measures propose the replacement of existing fuel oil-fired sources of heat with modern biomass boilers and heat pumps, and installation of solar collectors notably for the purpose of DHW preparation. All proposed measures of replacing fuel oil-fired sources of thermal energy for space heating and DHW preparation are cost-effective without support (FNPV > 0 and ENPV > 0). The result is expected given that fuel oil is an environmentally unacceptable energy product with a high CO<sub>2</sub> emissions factor (299.57 tonnes of CO<sub>2</sub>/GWh) compared to modern biomass or electricity. Furthermore, the price per unit of fuel oil is considerably higher than modern biomass price. Where heat pumps are used, the decisive element is, naturally, the fact that heat pump efficiency (SPF) is considerably higher than that of fuel oil-fired thermal energy sources.

Measures in the household sector envisage a gradual **replacement of liquefied petroleum gas (LPG) sources of heat** for space heating and DHW preparation in the period up to 2030 and between 2031 and 2050. The measures propose the replacement of existing LPG-fuelled sources of heat with modern biomass boilers and heat pumps, as well as the installation of solar collectors notably for the purpose of DHW preparation. All proposed measures of replacing LPG-fuelled thermal energy sources for space heating and DHW preparation are cost-effective without support (FNPV > 0 and ENPV > 0). The price per unit of LPG is higher than the fuel oil price per unit, so FNPV and ENPV amounts for the same proposed technologies (modern biomass boilers, heat pumps) are higher when replacing LPG-fuelled sources of heat than when fuel oil is replaced.

A series of measures has been proposed to **replace natural gas-fuelled sources of heat** (individual and central) for space heating and DHW preparation in the household sector in the period up to 2030 and between 2031 and 2050: condensing natural gas boilers, natural gas micro-CHP, heat pumps and modern biomass boilers, as well as the installation of solar collectors notably for DHW preparation. The measure involving solar collector installation for DHW preparation is cost-effective with public support (FNPV < 0 and ENPV > 0) in both periods under observation. The measure involving the replacement of existing standard natural gas boilers with condensing natural gas boilers is cost-effective (FNPV < 0 and ENPV > 0) without support in the period up to 2030, where a portion of outdated boilers with substantially more cost-effective condensing boilers (but their cost-effectiveness depends largely on the temperature regime, that is, on the flow/return water temperature in the heating system; however, it is important to renovate the building's external envelope, in turn providing for a lower temperature regime). In addition to condensing natural gas boilers, it is also important to install solar collectors for DHW preparation to at least partially increase the use of renewable energy sources.

The measure involving natural gas boiler replacement with natural gas micro-CHP for space heating is cost-effective with public support (FNPV < 0 and ENPV > 0) between 2031 and 2050. The measure is not cost-effective in the preceding, shorter period up to 2030. The economic NPV is positive because

of an additional contribution of electricity generation in micro CHP, in parallel with required heat generation.

The replacement of natural gas boilers with heat pumps for space heating and DHW preparation is cost-effective ( $FNPV < 0$  and  $ENPV > 0$ ) in both periods under observation. The decisive element here is a considerably higher efficiency if heat pumps (which, similar to condensing boilers, are a low-temperature heat source, more efficient in lower temperature regimes or at lower flow/return water temperatures within the heating system) are used.

Between 2031 and 2050, a portion of natural gas boilers is to be replaced by modern biomass boilers. The cost-benefit analysis has proven the measure to be cost-effective with support ( $FNPV < 0$  and  $ENPV > 0$ ). Modern biomass (wood pellets and wood chips) is considered a renewable energy source, with a low  $CO_2$  emissions factor and low primary energy factor compared to natural gas. However, the forecast price of modern biomass is higher than natural gas price, so the measure is not financially justified and requires public support to achieve the benefits mentioned above (the measure is to achieve primary energy and  $CO_2$  emission savings, increase the share of renewable energy sources, while also increasing the costs of drive energy product).

The **replacement of direct electric resistance space heating** with compression heat pumps in the household sector is definitely cost-effective ( $FNPV < 0$  and  $ENPV > 0$ ) with support in the period up to 2030; however, the measure is cost-effective without support between 2031 and 2050 in view of a considerably higher efficiency (SPF) of heat pumps compared to electric resistance space heating.

And finally, where household DHW preparation is concerned, it is important to prepare domestic hot water efficiently, avoiding direct DHW heating in electric boilers. The cost-benefit analysis demonstrated the cost-effectiveness of the measure involving electric DHW preparation boiler replacement with heat pumps and solar collectors.

### **SERVICE SECTOR – Analysis of the results of cost-benefit analysis**

As in the household sector, **a complete cessation of fuel oil use** as a drive energy product for space heating and DHW preparation is foreseen in the service sector by 2030 under the proposed measures. The measures propose the replacement of existing fuel oil-fired sources of heat with modern biomass boilers and heat pumps, and the installation of solar collectors notably for the purpose of DHW preparation (in service sector buildings where technically feasible and justified). All proposed measures of replacing fuel oil-fired sources of thermal energy for space heating and DHW preparation are cost-effective without support ( $FNPV > 0$  and  $ENPV > 0$ ). The result is expected given that fuel oil is an environmentally unacceptable energy product with a high  $CO_2$  emissions factor (299.57 tonnes of  $CO_2/GWh$ ) compared to modern biomass or electricity. Furthermore, the price per unit of fuel oil is considerably higher than modern biomass price. Where heat pumps are used, the decisive element is, naturally, the fact that heat pump efficiency (SPF) is considerably higher than that of fuel oil-fired thermal energy sources.

Under the proposed measures in service sector, **a complete cessation of fuel oil use** as a drive energy product for space heating and DHW preparation is foreseen by 2030. The measures propose the replacement of existing LPG-fuelled boilers as sources of heat with modern biomass boilers and heat pumps, and installation of solar collectors notably for DHW preparation (in service sector buildings where technically feasible and justified). All proposed measures of replacing LPG-fuelled thermal energy sources for space heating and DHW preparation are also cost-effective in the service sector without support ( $FNPV > 0$  and  $ENPV > 0$ ). The price per unit of LPG is higher than the fuel oil price per unit, so  $FNPV$  and  $ENPV$  amounts for the same proposed technologies (modern biomass boilers, heat pumps) are higher when replacing LPG-fuelled sources of heat than when fuel oil is replaced.

A series of measures has been proposed to **replace natural gas-fuelled sources of heat** for central space heating and DHW preparation in the sector in the period up to 2030 and between 2031 and

2050: condensing natural gas boilers, natural gas micro-CHP, heat pumps and modern biomass boilers, as well as the installation of solar collectors notably for DHW preparation.

The measure involving solar collector installation for DHW preparation is cost-effective with public support ( $FNPV < 0$  and  $ENPV > 0$ ) in both periods under observation.

The measure involving the replacement of standard natural gas boiler with condensing natural gas boilers for space heating and DHW preparation is cost-effective ( $FNPV < 0$  and  $ENPV > 0$ ) without support in both periods under observation. In addition to condensing natural gas boilers, it is also important to install solar collectors for DHW preparation (as a cost-effective measure with support) to at least partially increase the use of renewable energy sources.

The measure involving natural gas boiler replacement with natural gas micro-CHP for space heating in the service sector is not cost-effective with public support ( $FNPV < 0$  and  $ENPV < 0$ ) in both periods under observation.

The replacement of natural gas boilers with heat pumps for space heating and DHW preparation in the service sector is cost-effective ( $FNPV > 0$  and  $ENPV > 0$ ) in both periods under observation. The decisive element here is a considerably higher efficiency if heat pumps (which, similar to condensing boilers, are a low-temperature heat source, more efficient in lower temperature regimes or at lower flow/return water temperatures within the heating system) are used.

Between 2031 and 2050, a portion of natural gas boilers is to be replaced by modern biomass boilers in the service sector. The cost-benefit analysis has proven the measure to be cost-effective with support ( $FNPV < 0$  and  $ENPV > 0$ ). Modern biomass (wood pellets and wood chips) is considered a renewable energy source, with a low CO<sub>2</sub> emissions factor and low primary energy factor compared to natural gas. However, the forecast price of modern biomass is higher than natural gas price, so the measure is not financially justified and requires public support to achieve the benefits mentioned above (the measure is to achieve primary energy and CO<sub>2</sub> emission savings, increase the share of renewable energy sources, while also increasing the costs of drive energy product).

The replacement of natural gas boilers and connection of service sector customers to the district heating system wherever possible is a cost-effective measure without support.

The **replacement of direct electric resistance space heating** in the service sector with heat pumps is a cost-effective measure without support ( $FNPV > 0$  and  $ENPV > 0$ ) in both periods under observation periods in view of a considerably higher efficiency (SPF) of heat pumps compared to electric resistance space heating.

Similarly to the household sector, it is important to prepare domestic hot water efficiently in the service sector too, avoiding direct DHW heating in electric boilers. The cost-benefit analysis demonstrated the cost-effectiveness of the measure involving electric DHW preparation boiler replacement with heat pumps and solar collectors (in service sector buildings where technically feasible and justified).

### 8.1.3.2 DHS

When it comes to district heating systems, financial and economic NPV is calculated for total demand, irrespective of the sector (household sector, service sector, industrial sector) because the outcomes of the measure will affect overall demand as a whole.

The first measure, which must be implemented even though it has not been cost-benefit analysed, is increased efficiency and expansion of the distribution network of existing district heating systems in densely populated urban areas, that is, heat loss reduction in the existing distribution network and its expansion. It is planned to be implemented by 2030 at a total investment of HRK 1 650 000 000.00. The proposed measure would achieve savings of 68 590.66 tonnes of CO<sub>2</sub> and 334.53 GWh in primary energy savings.

Generation installations at existing district heating systems are to be modernised gradually in the period up to 2030 and between 2031 and 2050.

Figure III.9: shows investment (CAPEX) in the period of measure implementation, annual maintenance costs (OPEX) and annual costs of drive energy products for all technologies of individual systems within the DHS sector for two scenarios (BAU or baseline scenario, and SIM or alternative scenario) and the two periods under observation (up to 2030, and 2030–2050).

Figure III.9: DHS – 2030 and 2050 cost distribution, in mil. HRK

Trošak energenta	Cost of energy product

The results of completed financial and economic cost-benefit analysis for a total of 11 proposed measures relating to DHS generation installations in the period up to 2030, and between 2031 and 2050 are presented in Table III.26:.

Given that the measures are to be implemented over two periods (a shorter period up to 2030 and a longer one, between 2031 and 2050), some measures turned out not to be cost-effective in the shorter observation period (FNPV < 0 and ENPV < 0), while in the longer observation period the same measures proved cost-effective when supported (FNPV < 0 and ENPV > 0) or even without the necessary support (FNPV > 0 and ENPV > 0).

10	Replacement of natural gas boilers with biomass boilers	natural gas boilers	Biomass boilers	n/a	n/a	1 215.71	3 495.39
11	Replacement of natural gas boilers – geothermal energy exploitation	natural gas boilers	geothermal energy	-7 890.91	-10 009.02	-920.14	387.72

The replacement of natural gas boilers poses the greatest challenge given that 72.78% of the total energy delivered in 2019 was produced in natural gas boilers. The proposed **measures to replace natural gas boilers** are as follows: water-to-water heat pumps, high-efficiency natural gas cogeneration, industrial waste heat utilisation, energy-from-waste, solar energy harnessing, high-efficiency biomass cogeneration, biomass boilers and geothermal energy exploitation.

The measure of replacing natural gas boilers with water-to-water compression heat pumps is cost-effective (FNPV > 0 and ENPV > 0) without support in both periods under observation, which is in fact fitting given the high efficiency of water-to-water heat pumps (SPF) compared to natural gas boilers.

The replacement of natural gas boilers with high-efficiency natural gas cogeneration is proposed as another cost effective measure (FNPV > 0 and ENPV > 0) for the period between 2031 and 2050 in view of the efficient use of natural gas as the driving energy product, whose input leads to greater output (simultaneous generation of electricity and thermal energy) compared to natural gas boilers.

Geothermal energy exploitation as an alternative to using natural gas boilers is a cost-effective measure only when supported (FNPV < 0 and ENPV > 0) due to the extremely high investment costs. The same is true for industrial waste heat utilisation.

Energy-from-waste, solar energy utilisation, high-efficiency biomass cogeneration and biomass boilers are all cost-effective measures with no need for public support (FNPV > 0 and ENPV > 0) aimed at replacing existing natural gas boilers between 2031 and 2050. Biomass (wood chips) is considered a renewable energy source, with a low CO<sub>2</sub> emissions factor and low primary energy factor compared to natural gas.

The **measure of natural gas cogeneration replacement** with high-efficiency natural gas cogeneration is also cost-effective with no need for public support (FNPV > 0 and ENPV > 0) in the 2031–2050 period under observation. In the observation period up to 2030, due to its shortness, the cost-benefit analysis found this measure not to be cost-effective (FNPV < 0 and ENPV < 0).

It is important to note that both proposed measures (biomass boilers and heat pumps), which are aimed at replacing **fuel oil boilers**, are cost-effective without support (FNPV > 0 and ENPV > 0). Biomass is a renewable energy source with a low CO<sub>2</sub> emissions factor and a low primary energy factor, while heat pumps operate by extracting a certain amount of heat from the environment, which is considered a renewable energy source, and by using electrical energy to bring the heat taken from the environment to a higher temperature level.

## 8.2 SENSITIVITY ANALYSIS

The results of the economic analysis presented above in respect of different heating and cooling alternatives depend on changes in the parameters covered by the analysis, in particular on developments in the prices of energy products and CO<sub>2</sub> emissions. Therefore, in order to ensure that the analysis of potential is complete, it is also necessary to conduct a sensitivity analysis to identify the parameters whose variations have a significant impact on the cost-effectiveness of a measure, and thus also on the NPV amount. The sensitivity analysis is aimed at examining uncertainty or a range of the outcomes. To this end, the impact of possible changes in technical and economic assumptions is investigated and the effect of such changes on the results of the cost-benefit analysis is examined from a microeconomic and macroeconomic perspective. These are usually increases/decreases in the unit cost of technologies, increases in energy product prices, variations in CO<sub>2</sub> prices, changes in discount rates, etc. The results of the analysis serve for estimating the absolute change in NPV in an individual scenario caused by a change to a certain parameter and also to assess the extent of any changes in the relationships (relative advantages) between alternative scenarios.

The results of the sensitivity analysis in respect of a change in individual critical variables are presented below.

The sensitivity analysis was conducted separately to obtain results for the measures up to 2030, and separately for the measures in the 2031–2050 period.

The following parameters were varied in the sensitivity analysis:

- investment costs (CAPEX), +/-20%,
- higher price of electricity and energy products (Table III.22:),
- higher price of CO<sub>2</sub> emissions (Table III.22:), and
- discount rate (10% financial discount rate and 4% economic discount rate).

A total of seven calculations is performed. Of the above parameters, variations in CO<sub>2</sub> prices and changes in the social discount rate have an impact on the outcome of the economic analysis. The remaining parameters primarily affect the outcome of the financial analysis.

An increase in investment costs for all the technologies included in the alternative scenario is presumed. The assumption of a decrease in investment costs makes sense only in relation to renewable technologies and industrial waste heat as further research and economies of scale may be presumed for those technologies.

Higher energy product prices and CO<sub>2</sub> emissions are presumed to be possible.

Results of the conducted analysis are shown below for individual systems and DHSs. The results of individual calculations are presented in their entirety in the Annex (Table 0.30 – Table 0.36).

The proposed measures for households show no major sensitivity to an increase in investment costs, so a 20% increase in costs does not affect the final outcome in respect of the cost-effectiveness of the measure (no new negative NPVs). In services, however, certain measures are sensitive to changes in investment costs, specifically: solar heating combined with a condensing boiler after the PP1 measure is implemented (2031–2050) and the installation of solar collectors for DHW preparation (up to 2030). In the case of DHS, only the implementation of the measure for replacing natural gas cogeneration with natural gas HEC shows a more significant response to changes in investment costs.

Reducing the investment value would lead to a shift in the results for several measures in the household sector, such as natural gas micro-CHP, the installation of solar collectors for DHW preparation and replacement of natural gas boilers with modern biomass between 2031 and 2050, and for the measure involving an increase in the share of heat pumps vs. electric resistance heating, such as the installation of heat pumps by 2030. In the service sector, the same would be true in respect of the outcome of the measure involving solar heating combined with a condensing boiler after the PP1 measure is implemented for heating up to 2030, and for DHW between 2031 and 2050. With regard to DHS, there is no significant impact where the measure's cost-effectiveness is concerned: the most sensitive measure is the replacement of natural gas cogeneration with natural gas HEC between 2031 and 2050.

Increases in energy product prices most frequently affected NPV growth under respective measures, indicating that the prices of fossil fuels increased more under the BAU scenario than under alternative scenarios in the same period. The measure involving the replacement of natural gas boilers with modern biomass proved to be the most sensitive to changes in the prices of energy products for households and services.

An increase in emissions prices has the effect of actually increasing the monetised benefits of reducing CO<sub>2</sub> emissions. For households, the use of measures involving natural gas micro-CHP and the installation of solar collectors for DHW preparation becomes economically justified when higher emissions price are applied. For services, such measures are those involving the replacement of natural gas boilers with modern biomass boilers and solar heating combined with a condensing boiler after

the PP1 measure is implemented, and for DHSs, those involving the replacement of natural gas boilers with water-to-water compression heat pumps.

The measure for the replacement of natural gas boilers with modern biomass boilers (in the period up to 2050) proved to be the most sensitive to changes in the discount rate for households and services. Increasing the discount rate to 7% did not affect the cost-effectiveness of the measures. For households, reducing the financial discount rate to 3% leads to the cost-effectiveness of the measure involving the installation of solar collectors for DHW preparation; when it comes to services, it is the measure involving solar heating combined with a condensing boiler after the PP1 measure is implemented for both heating and DHW preparation.

By reducing the financial discount rate to 3% in the case of DHSs, three measures become financially viable with no need for support: the replacement of natural gas cogeneration with high-efficiency natural gas cogeneration, as well as the replacement of natural gas boilers with high-efficiency natural gas cogeneration, and industrial waste heat utilisation.

Increasing the economic discount rate to 4% reduces the economic outcome of the measures in most cases, except where the cost of CO<sub>2</sub> emissions is higher exceptionally under the BAU scenario than under the alternative scenario (e.g. replacement of central firewood boilers with central modern biomass boilers). Neither in individual systems nor in DHSs does an increase in the economic discount rate affect the outcome in terms of changes in the economic viability of the measures.

### 8.3 DISCUSSION AND CONCLUSION

The aim of this Comprehensive Assessment, which needs to be prepared regularly every five years under Article 14 of Directive 2012/27/EU, has been to determine the economic potential for covering heating/cooling needs in household, service and industrial sectors in an energy-efficient manner, primarily by using as many renewable energy sources as possible and waste heat. The content of the Comprehensive Assessment is laid down in Annex VIII to Directive 2012/27/EU. The net present value method was used as part of the cost-benefit analysis for assessing the cost-effectiveness of the investment under the proposed measures. The main outcome of the cost-benefit analysis consists in the most cost-efficient solutions for meeting heating and cooling needs.

A reduction of CO<sub>2</sub> emissions, use of energy from renewable energy sources, energy efficiency, and energy interconnection were also among the objectives considered in the Integrated National Energy and Climate Plan for the Republic of Croatia for 2021–2030. Among other things, that document sets Croatia's objectives and targets for 2030 in terms of reducing greenhouse gas emissions and increasing the share of renewable energy sources in final energy consumption (industry, transport, general consumption (households, services, agriculture, construction)).

The ultimate goal is to achieve climate neutrality in Croatia by 2050. While the share of fossil fuels in 2030 will still be considerable, the use of fossil fuels for heating/cooling purposes should be kept to a minimum by 2050.

Figure III.10: and Figure III.11: provide an overview of the energy products to cover space heating/cooling needs and DHW preparation in the three observed sectors (household, services, industry) for the following two scenarios: BAU (reference, baseline scenario) scenario and SIM scenario (scenario with integrated measures) for 2019–2050.

In the period between 2019 and 2050, the SIM scenario shows a decrease in the consumption of firewood, a gradual increase in the consumption of modern biomass (pellets and wood chips), a decline in fossil fuel consumption (natural gas, fuel oil and LPG), the use of biomethane and hydrogen in the gas grid, and greater use of geothermal energy and solar energy.

Figure III.12: provides an overview of the structure of energy products and technologies in the total energy delivered from the DHS in the reference year 2019, as well as in 2030 and 2050.

The projected reduction in the consumption of energy delivered from the DHS results from the following:

- increasing the efficiency (reducing heat losses) and expanding the distribution network of existing district heating systems in densely populated urban areas;
- modernising the generation installations of existing district heating systems;
  - using geothermal energy sources;
  - high-efficiency cogeneration from natural gas and biomass (wood chips);
  - energy-from-waste;
  - using renewable energy sources through heat pumps and, to a lesser extent, solar collectors;
  - utilising waste heat from industrial installations.

Figure III.12: HOUSEHOLD, SERVICE AND INDUSTRIAL SECTORS – DHS – SIM scenario (scenario with integrated measures) – overview of energy product/technology structure – 2019–2050

Based on the outcome of the cost-benefit analysis, certain measures are cost-effective with no need for public support:

- INDIVIDUAL SYSTEMS<sup>29</sup> – HOUSEHOLD SECTOR:
  - replacement of central fuel oil boilers with central modern biomass boilers for space heating and DHW preparation, and installation of solar collectors for DHW preparation (by 2030);
  - replacement of central fuel oil boilers with heat pumps for space heating and DHW preparation, and installation of solar collectors for DHW preparation (by 2030);
  - replacement of central LPG boilers with central modern biomass boilers, and installation of solar collectors for DHW preparation (by 2050);
  - replacement of central LPG boilers with heat pumps, and installation of solar collectors for DHW preparation (by 2050);
  - replacement of standard natural gas boilers with condensing natural gas boilers for space heating and DHW preparation (by 2030);
  - replacement of natural gas boilers with heat pumps;
  - replacement of individual electric boilers for DHW preparation with heat pumps and solar collectors;
  
- INDIVIDUAL SYSTEMS – SERVICE SECTOR:
  - replacement of central fuel oil boilers with central modern biomass boilers for space heating and DHW preparation, and installation of solar collectors for DHW preparation (by 2030);
  - replacement of central fuel oil boilers with heat pumps for space heating and DHW preparation, and installation of solar collectors for DHW preparation (by 2030);
  - replacement of central LPG boilers with central modern biomass boilers, and installation of solar collectors for DHW preparation (by 2030);
  - replacement of central LPG boilers with heat pumps, and installation of solar collectors for DHW preparation (by 2030);
  - replacement of standard natural gas boilers with condensing natural gas boilers for space heating and DHW preparation (by 2030);
  - replacement of natural gas boilers with heat pumps;
  - connection of service sector consumers to the DHS (by 2050);
  - replacement of individual electric space heaters with heat pumps (by 2050);
  - replacement of individual electric boilers for DHW preparation with heat pumps and solar collectors (by 2050);
  
- DISTRICT HEATING SYSTEMS:
  - replacement of fuel oil boilers with biomass boilers (by 2030);
  - replacement of fuel oil boilers with water-to-water heat pumps (by 2030);
  - replacement of natural gas cogeneration with high-efficiency natural gas cogeneration (by 2050);
  - replacement of natural gas boilers with water-to-water compression heat pumps (by 2050);
  - replacement of natural gas boilers – waste heat utilisation (by 2050);

---

<sup>29</sup> Each consumer has their own separate source of heating and/or cooling energy.

- replacement of natural gas boilers – solar energy harnessing (do 2050.),
- ;
- replacement of natural gas boilers with high-efficiency biomass cogeneration (by 2050);
- replacement of natural gas boilers with biomass boilers (by 2050).

Due to the shorter length of the observation period, all the above measures – except those involving the replacement of fuel oil boilers – are not cost-effective in the period until 2030 but they become cost-effective in the period between 2031 and 2050.

The measures which are cost-effective with public support, where the economic NPV is positive and the financial NPV negative, are provided in tabular form in Part IV.

In order to carry out decarbonisation in household, service and industrial sectors, solely in terms of covering the needs for space heating, DHW preparation or space cooling, it is necessary to:

- build all new buildings as nearly zero-energy buildings (NZEB), where at least 30% of the annual energy delivered for the operation of the building's technical systems must be provided from the renewable energy sources of the building (requirement laid down in the *Technical regulation amending the Technical regulation on energy economy and heat retention in buildings* (NN No 102/2020));
- carry out major renovation<sup>30</sup> and reconstruction<sup>31</sup> of existing buildings – the renovation and reconstruction of existing buildings is extremely important as it enables the efficient use of low-temperature energy sources, notably of compression heat pumps as decentralised heat sources, as well as of other low-temperature heat sources within the DHS (industrial waste heat utilisation); external building envelope retrofitting enables the transition to a low-temperature heating system, entailing a much more efficient operation of low-temperature energy sources at low consumption of drive energy products, and low heat losses in all segments of the heating system (production subsystem, distribution subsystem, spatial heat emissions subsystem);
- implement the building automation and control system in both new and existing non-residential buildings with a space heating system, combined space heating and ventilation system, space cooling system, combined space cooling and ventilation system with a rated heating/cooling capacity exceeding 290 kW (service sector) (requirement laid down in the *Technical regulation amending the Technical regulation on energy economy and heat retention in buildings* (NN No 102/2020), which will enter into force on 1 January 2025), with the main aim of ensuring the optimal production, distribution, storage and use of energy for heating/cooling purposes;
- use electricity generated from renewable energy sources (wind farms, hydropower plants, photovoltaics) to drive compression heat pumps;
- strive to primarily use energy delivered from district heating systems (DHS) for heating or DHW preparation in densely populated urban areas, while taking the following mandatory steps:
  - expanding the distribution network of existing district heating systems in densely populated urban areas;
  - renovating the existing distribution network (appropriate thermal insulation serving to reduce heat losses in the distribution network);

<sup>30</sup> Major building renovation means the renovation or reconstruction of a building where more than 25% of the building envelope undergoes renovation.

<sup>31</sup> Reconstruction of an existing building means a partial or complete renovation of 75% or more of the envelope of the heated part of the building.

- modernising the generation installations of existing district heating systems by combining different heat generation technologies:
  - using geothermal energy sources;
  - energy-from-waste;
  - utilisation of waste heat from industrial installations;
  - utilisation of renewable energy sources through the use of heat pumps (heating plants by rivers) and, to a lesser extent, solar collectors;
  - high-efficiency cogeneration from natural gas and biomass (in 2050, there will be significantly fewer gas boilers compared to the reference year 2019, with biogas and hydrogen blended into natural gas);
  - use of a DHS heat-carrying medium in the summer to power the central absorption chiller for cooling spaces in larger non-residential buildings (e.g. hospitals, hotels, shops, etc.) which are already connected to the district heating system – removal of compression chillers with environmentally unacceptable refrigerants and installation of absorption chillers powered by hot water from the DHS (remains as an option to be elaborated);
- increasing the share of biomethane and hydrogen in the existing gas grid (costs of biomethane and hydrogen production have not been considered in this Comprehensive Assessment).

In view of the sensitivity analysis, it is important to take the following into account:

- measures in the service sector are more sensitive to increases in investment costs than those in the household sector;
- reducing the investment value would lead to a shift in the results for several measures in the household and service sector;
- increases in energy product prices most often affected the growth of NPV of the measures, which indicates that the prices of fossil fuels in the BAU scenario increased more than those in alternative scenarios in the same period;
- an increase in emissions prices has the effect of increasing the monetised benefits of reducing CO<sub>2</sub> emissions, so certain measures that were not economically viable become viable measures;
- increasing the discount rate to 7% did not affect the cost-effectiveness of the measures. By reducing the financial discount rate to 3%, certain measures that were not cost-effective with a rate of 5% become cost-effective;
- neither in individual systems nor in DHSs does an increase in the economic discount rate affect the outcome in terms of changes in the economic viability of the measures.

The comprehensive assessment of the potential for efficient heating and cooling in Croatia under Annex VIII to Directive 2012/27/EU shows notably the existence of great potential for an efficient district heating system in Croatia, based on the use of renewable energy sources (primarily geothermal energy) and high-efficiency cogeneration from natural gas and biomass, as well as considerable potential through the application of measures relating to individual systems in household and service sectors.

## **DIO IV. POTENTIAL NEW STRATEGIES AND POLICY MEASURES**

---

## 9 OVERVIEW OF NEW LEGISLATIVE AND NON-LEGISLATIVE POLICY MEASURES

This chapter presents potential new strategies and strategic policy measures<sup>32</sup> aimed at realising the economic potential for heating and cooling efficiency, identified in Part III ANALYSIS OF THE ECONOMIC POTENTIAL FOR EFFICIENT HEATING AND COOLING, together with their foreseen:

- greenhouse gas emission reductions;
- primary energy savings in GWh per year;
- impact on the share of high-efficiency cogeneration;
- impact on the share of renewables in the national energy mix and in the heating and cooling sector;
- links to national financial programming and cost savings for the public budget and market participants;
- estimated public support measures (if any), with their annual budget and identification of the potential aid element.

As part of the cost-benefit analysis conducted, two financial parameters were obtained for each measure: financial NPV (FNPV) and economic NPV (ENPV), which may serve to identify policy measures to support or promote those solutions, as well as to remove existing or planned measures if the cost-benefit analysis finds the observed solutions not to be socially justified.

Based on the two economic parameters stated above, policy measures were defined using the following rules:

- $FNPV < 0$  and  $ENPV > 0$  → socially justified measure requiring public support;
- $FNPV > 0$  and  $ENPV > 0$  → cost-effective measure not requiring support (if the measure is already receiving support, public authorities should consider whether the existing support is appropriate and whether it should be reduced);
- $ENPV < 0$  and  $ENPV < 0$  → the measure is not justified from a social perspective (if the measure is already receiving support, the withdrawal of support should be considered).

Based on the results of the analysis of the economic potential for efficient heating and cooling (DIO III), the following potential new strategies and strategic measures have been obtained (listed clearly in Table IV.1: with corresponding savings):

- INDIVIDUAL SYSTEMS<sup>33</sup> – HOUSEHOLD SECTOR:
  - replacement of natural gas boilers with combined heat and power (micro-CHP) system, fuelled by natural gas (between 2030 and 2050);
  - installation of solar collectors for DHW preparation where natural gas central boilers are used for DHW preparation;
  - replacement of natural gas boilers with modern biomass boilers for space heating and DHW preparation, and installation of solar collectors for DHW preparation;

<sup>32</sup> This overview includes financing measures and programmes that may be adopted over the period of the comprehensive assessment, not prejudging a separate notification of the public support schemes for a State aid assessment.

<sup>33</sup> Each consumer has their own separate source of heating and/or cooling energy.

- replacement of individual electric space heaters with heat pumps (by 2030);
- INDIVIDUAL SYSTEMS – SERVICE SECTOR:
  - installation of solar collectors for DHW preparation where natural gas central boilers are used for DHW preparation;
  - replacement of natural gas boilers with modern biomass boilers for space heating and DHW preparation, and installation of solar collectors for DHW preparation (where technically feasible and justified in service sector buildings);
- DISTRICT HEATING SYSTEMS<sup>34</sup> – increased efficiency and expansion of the distribution network of existing district heating systems in densely populated urban areas;
- DISTRICT HEATING SYSTEMS – modernisation of generation facilities of existing district heating systems:
  - replacement of natural gas boilers – industrial waste heat utilisation;
  - replacement of natural gas boilers – geothermal energy exploitation.

In order to reduce the consumption of fossil fuels (in this case, natural gas) by 2030, it is important to encourage the installation of solar collectors for DHW preparation in both household-sector and service-sector buildings where this is technically feasible and justified (e.g. hospitals, hotels).

Fuel oil, as an environmentally highly unacceptable fossil fuel with a high CO<sub>2</sub> emissions factor, should be eliminated from use entirely by 2030 in the household and service sectors, and as the fuel used to power boilers in the DHS.

An identical measure in the household and service sectors, which has the values FNPV < 0 and ENPV > 0 and thus requires public support, refers to the replacement of natural gas boilers with modern biomass boilers for the purpose of space heating and DHW preparation, and the installation of solar collectors for DHW preparation between 2030 and 2050.

After fuel oil is eliminated from use, it is also important to gradually reduce the consumption of natural gas between 2030 and 2050. Modern biomass (wood pellets and wood chips) is considered a renewable energy source with a low CO<sub>2</sub> emissions factor (carbon-neutral fuel, assuming that the burning of biomass releases the same amount of CO<sub>2</sub> as is captured from the atmosphere through photosynthesis) and a low primary energy factor compared to natural gas. However, the projected price of modern biomass is slightly higher than the price of natural gas, so the measure is not financially justified and requires public support on account of the above benefits.

With regard to the modernisation of district heating system production facilities, the cost-benefit analysis revealed two measures requiring public support. The measure that must certainly be implemented first is the reduction of heat losses in the DHS distribution network. This is to be followed by a modernisation of the production facilities of existing district heating systems. The measure achieving the most significant savings, while requiring public support, is the exploitation of geothermal energy. The total potential power of geothermal energy sources at 52 sites is estimated at 546 MW<sub>e</sub> and almost 2 000 MW<sub>t</sub>, while the installed thermal capacity is planned to be 181.73 MW under the proposed measure. In addition, the provision of public aid is very important for the measure involving industrial waste heat utilisation.

Croatia must move towards increased development and expansion of the DHS, particularly in densely populated urban areas (avoiding individual systems, which are based primarily on the combustion of fossil fuel, as well as biomass – no form of combustion in urban areas), by using available waste heat (industrial waste heat, energy-from-waste) and renewable energy sources (geothermal energy, solar

---

<sup>34</sup> District heating systems used for heat distribution from the source (generation installation) to consumers.

energy, biomass) and by applying only high-efficiency cogeneration from natural gas and biomass, in order to obtain more from the fuel input (simultaneous generation of electricity and thermal energy).

Table IV.1: Overview of strategic measures and corresponding savings

Short description of potential new strategy or policy measure	Objective of new strategy or policy measure	Expected reduction in CO <sub>2</sub> emissions [tonne of CO <sub>2</sub> /a]	Primary energy savings [GWh/a]	Impact on high-efficiency cogeneration share	Impact on share of renewables in the national energy mix and the heating and cooling sector	Link to national financial programming	Public support measures

Short description of potential new strategy or policy measure	Objective of new strategy or policy measure	Expected reduction in CO <sub>2</sub> emissions [tonne of CO <sub>2</sub> /a]	Primary energy savings [GWh/a]	Impact on high-efficiency cogeneration share	Impact on share of renewables in the national energy mix and the heating and cooling sector	Link to national financial programming	Public support measures
<b>exploitation of geothermal energy</b>	reduction of CO <sub>2</sub> emissions,- increase of RES share				amounting to 264.94 GWh	centralised thermal energy production systems	

It is clear from the measures presented in the table above that they have already been included in national programmes (NECP, NRRP); in other words, increasing energy efficiency and improvements in renewable energy in the heating and cooling sector are already linked to national goals set by Croatia. These measures will be elaborated further through those very programmes, which will describe and define more precisely the annual budgets and potential aid elements.

### 9.1.1 A LOOK AT ENERGY-FROM-WASTE

Efficient waste management is ensured by the Croatian Government and the Ministry of Economy and Sustainable Development (formerly the Ministry of Environment and Energy; hereinafter: the Ministry), as the ministry responsible for waste management, by laying down waste management measures, issuing legislation and strategic planning documents.

Croatia's core documents related to waste management are as follows:

- *Sustainable Waste Management Act (NN Nos 94/13, 73/17, 14/19, 98/19),*
- *Waste Management Strategy of the Republic of Croatia (NN No 130/05),*
- *Waste Management Plan of the Republic of Croatia for 2017–2022 (NN No 3/17),*
- *Environmental Protection Act (NN Nos 80/13, 153/13, 78/15, 12/18, 118/18), and*
- *National Environmental Protection Strategy of the Republic of Croatia (NN No 46/2002).*

These documents are aligned with European legislation and strategies and based on the principles advocated in the EU legislative and strategic framework. Their purpose is to establish a framework for reducing the amount of waste generated by Croatia, as well as the sustainable management of the waste already generated in accordance with the principles of the circular economy and bioeconomy. The documents create frameworks within which sustainable waste management processes are implemented and planned, while defining the following:

- basic objectives and measures relating to waste management,
- measures concerning hazardous waste management, and
- guidelines for waste recovery and disposal.

In order for the establishment and implementation of a sustainable system to be feasible, waste management and circular economy activities need to be implemented at all levels (national to local), while being reflected in other sectors, such as water management, mining, veterinary medicine, physical planning, etc.

As of 1 January 2019, the Croatian Agency for the Environment and Nature (CAEN) was merged with the Ministry, so its activities are performed by the Institute for Environmental and Nature Protection of the Ministry (hereinafter: the Institute). The Institute collects, consolidates and keeps data in accordance with the *Sustainable Waste Management Act* and implementing regulations, maintains the waste management information system, prepares reports on the state of waste management and carries out reporting in the field of waste management as required by EU regulations.

The implementing body at state level is the Environmental Protection and Energy Efficiency Fund (hereinafter: the Fund). The Fund provides additional resources for the financing of projects, programmes and similar activities in the field of environmental protection and improvement, has the

authority to issue administrative acts related to the payment of fees and special charges, and keeps a register of taxpayers.

At the regional and local level, waste management is the responsibility of the local and regional self-government unit (hereinafter: the LRSGU), which is required to provide the conditions and ensure the implementation of prescribed waste management measures in its area of governance. Multiple LRSGUs may ensure, by mutual agreement, the joint implementation of waste management measures. In municipalities/cities, waste management tasks are carried out by different administrative bodies (usually single administrative departments).

These public and administrative bodies implement legislative and strategic frameworks related to waste management, as set out in the EU strategic frameworks. Among them is the order of priorities in waste management, defined in EU Directive 2008/98/EC on waste, which presents the hierarchy and most preferred steps in the waste management process. The most preferred option is waste prevention, followed by preparation for re-use, recycling and other recovery procedures, while the waste disposal procedure, which includes landfilling, is the least preferred waste management option.
