Slovenia

Disclaimer: The graphs below show data available in the EU Building Stock Observatory; some data was not available for this specific country.

Building Stock Characteristics

The average age of buildings and the share of new buildings in the total stock represent good indicators of the average efficiency of the building stock: the higher the share of recent dwelling, i.e. built with more efficient standards, the higher the energy performance of the stock.

Sources: Estimation Notes

The EPBD requires all new buildings from 2021 (public buildings from 2019) to be nearly zero-energy buildings (NZEB). According to Article 2 "nearly zero-energy building" means a building that has a very high energy performance, as determined in accordance with Annex I. The nearly zero or very low amount of energy required should be covered to a very significant extent from renewable sources, including sources produced on-site or nearby.

Slovenia has a nearly zero-energy buildings (NZEB) in the legislation.

As concrete numeric thresholds or ranges are not defined in the EPBD, these requirements leave room for interpretation and thus allow Member States to define their nearly zero-energy buildings (NZEB) in a flexible way, taking into account their country-specific climate conditions, primary energy factors, ambition levels, calculation methodologies and building traditions. This is also the main reason why existing nearly zero-energy buildings (NZEB) definitions differ significantly from country to country. It is thus a challenging task to find a common denominator to define nearly zero-energy buildings (NZEB) at a European scale. The EU-project ZEBRA2020 sets a clear methodology for how nearly zero-energy buildings (NZEB) are defined in the context of market tracking: the nearly zero-energy buildings (NZEB) radar graphic*. The nearly zero-energy buildings (NZEB) radar allows combining qualitative and quantitative analysis of building standards in a specific region. The nearly zero-energy buildings (NZEB) radar clusters energy efficiency qualities in 4 different categories that have been defined at national level by experts:

1. Net zero energy buildings / Plus energy buildings
2. Nearly zero-energy buildings (NZEB) according to national definitions
3. Buildings with an energy performance better than the national requirements in 2012
4. Buildings constructed/renovated according to national minimum requirements in 2012

* More information on the methodology are available here : http://www.zebra-monitoring.enerdata.eu/ (http://www.zebra-monitoring.enerdata.eu/)

Energy Use in Buildings

The following graphs display the energy consumption of households for all end-uses, namely space and water heating, cooling, cooking, lighting and appliances. Energy consumption is measured at normal climate (i.e. corrected for climatic variations) to avoid yearly fluctuations due to climatic variations from one year to the other, and thus to have consistent trends.

The energy consumption in residential buildings is higher compared to the EU average. The energy consumption in non-residential buildings is higher compared to the EU average.

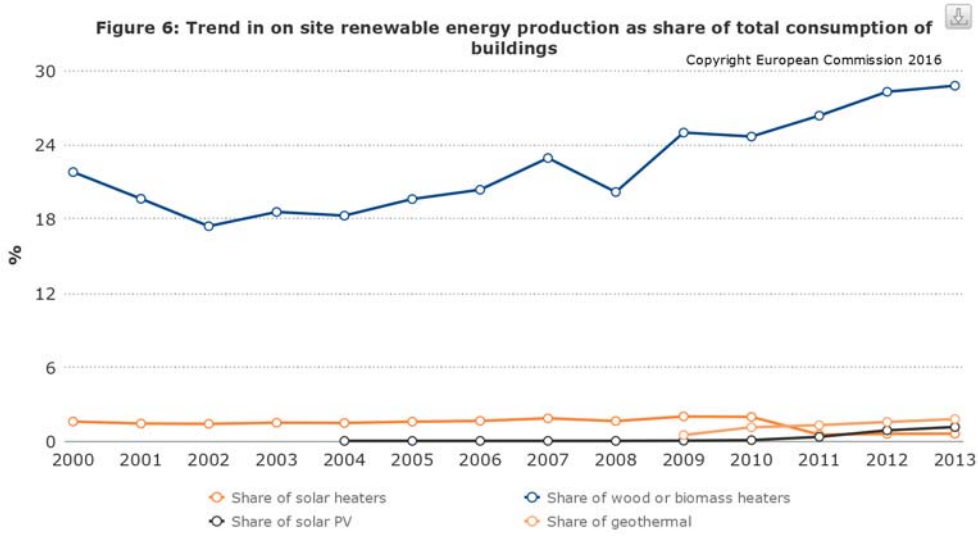
On-site Renewable Energy

On the long run the building stock in EU must be energy neutral, meaning that all the energy demand is covered by on-site renewable energy generation. The Renewable Energy Directive (RES Directive) establishes an overall policy for the production and promotion of energy from renewable sources in the EU. It requires the EU to fulfil at least 20% of its total energy needs with renewables by 2020 - to be achieved through the attainment of individual national targets. Slovenia has set national renewable energy requirements per specific renewable energy source.

Figure 7 shows the share of renewable energy generation compared to total final energy consumption of buildings. The figure shows that today on-site energy only covers a small share of total consumption.



Sources: Own calculations Notes

Renewable energy generation is increasing rapidly in Europe as well as in Slovenia. Due to a strong cost decrease of solar PV, since 2005 solar electricity production in Europe has grown with on average 56% per year.

Appliances

The introduction of eco-design requirements has compensated for the growth of appliances' energy use by demanding more efficient appliances. Following eco-design requirements for appliances like refrigerators, freezers, washing machines and more, energy consumption of these individual appliances has decreased significantly.

Like in most countries in Europe, the energy consumption of appliances in Slovenia is relatively small compared to heating. The number of appliances in Slovenia is rising. For 'standard' equipment, like refrigerators and television sets, the penetration is close to 100%. The owner ship rate of more luxurious equipment like dishwashers and dryers is steadily rising. The average number of computers in households is rapidly growing.

Building Performance Certification

The Energy Performance Certifications were introduced by the EPBD in 2002; while implementation at the Member States level was completed beginning of 2009. In 2014, in Slovenia , the share of buildings with an energy performance certificate registered is 4.1 % for the residential building stock. The table below presents the compliance level regarding the production of EPCs for new and existing buildings reported by the government of Slovenia to the European Commission for the year 2014.

Figure 9: Compliance level regarding production of the EPC (2014)

New buildings	90 %
Sold buildings	90 %
Rented buildings	90 %
Public buildings	70 %

Sources: ICF Notes

Existing buildings: Like in most countries, in Slovenia, over a half of all buildings with registered certificates have for energy class D or lower. The share of buildings with the lowest energy class in 2015 was 82% for residential buildings.

Social Aspects

Slovenia is one of the countries without an official definition for "energy poverty". Energy poverty is generally described as the "inability to keep homes adequately warm", an indicator monitored by EU statistics on income and living conditions (EU-SILC), which can be correlated with a low household income, high energy costs and energy inefficient homes. Data shows that in 2014, 5.6% of the total population in Slovenia was unable to keep an adequate level of warmth in their houses and 20.3% of the population faced difficulties in paying their utility bills. The corresponding EU28 average values were 10.2% and 10.2%. The evolution of the two indicators since 2004 is displayed in the following graphs.

Breakdown of dwellings by ownership & tenure

This indicator shows the shares of multifamily dwellings by ownership & tenure: owner occupied, rent at market price and rent at reduced price or free. In the EU, the largest group of inhabitants live in owner occupied dwellings - they represent 70% of dwelling users (EUROSTAT, 2014). In Slovenia, they make up for 77% of inhabitants (EUROSTAT, 2014).

The ownership of a dwelling defines among others whether the users can influence the energy performance of the building which has crucial environmental and social impacts (e.g. Landlord/Tenant Dilemma). Further social impacts are defined by the share of rent at reduced price or free that averages within the overall housing stock across the EU at about 11% (EUROSTAT, 2014).

Rent at market price represent 6% of the inhabitants in Slovenia (EUROSTAT, 2014) and they have less possibilities than owners to influence the current state of the building stock.

The general issue is whether the ownership of a comfortable dwelling is affordable for inhabitants and if the number of rent at reduced price or free, which makes up for 17% of the building stock in Slovenia (EUROSTAT, 2014), is enough or not to meet the existing demand. As the largest part of the building stock is owner occupied in Slovenia, we can assume that affordability of housing is relatively high.
