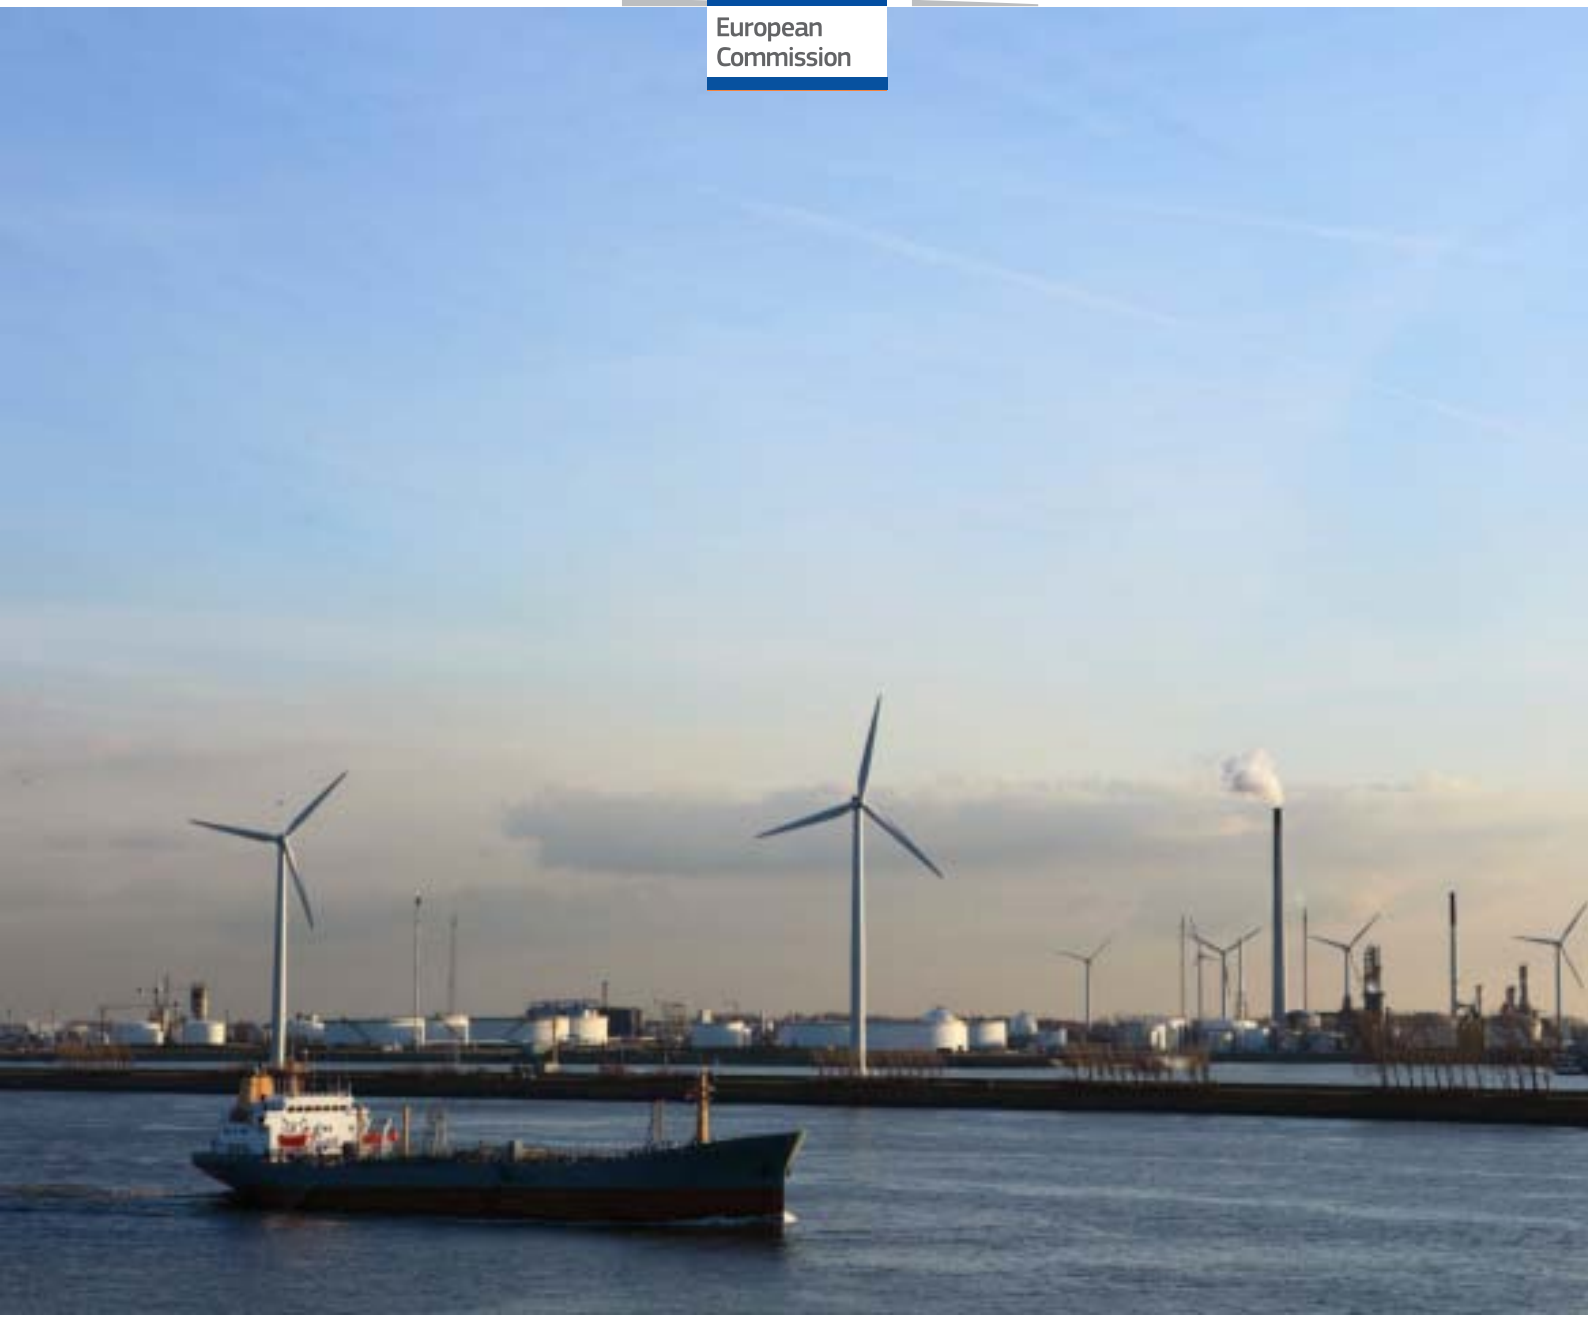
European Commission



EU ENERGY, TRANSPORT AND GHG EMISSIONS

TRENDS TO 2050

REFERENCE SCENARIO 2013

This publication was prepared for the Directorate-General for Energy, the Directorate-General for Climate Action and the Directorate-General for Mobility and Transport by the E3M-Lab of the Institute of Communication and Computer Systems at the National Technical University of Athens (ICCS-NTUA), Greece, in cooperation with the International Institute for Applied Systems Analysis (IIASA) and EuroCARE and represents those organisations' views on energy, transport and GHG emissions facts, figures and projections. These views should not be considered as a statement of the Commission's or the Directorate-General's views.

RES-E	Renewable Energy Sources for Electricity
RES-H&C	Renewable Energy Sources for Heating and Cooling
RES-T	Renewable Energy Sources for Transport
RP	Resource-Production
TEN-T	Trans-European Transport Network
TYNDP	Ten-Year Network Development Plan (adopted by ENTSO-E)
USGS	United States Geological Survey

INTRODUCTION

1. Introduction

Purpose of the publication

This report is an update and extension of the previous trend scenarios for development of energy systems taking account of transport and GHG emissions developments, such as the "European energy and transport - Trends to 2030" published in 2003 and its 2005, 2007 and 2009 updates[1]. The purpose of this publication is to present the new "EU Reference scenario 2013" ("Reference scenario" later in the text). This Reference scenario was finalised in July 2013. It focuses even more than previous ones on the energy, transport and climate dimensions of EU developments and the various interactions among policies, including now also specific sections on emission trends not related to energy. Its time horizon has been extended up to 2050. It reports for the first time on EU28 including Croatia. Moreover, the modelling process has included four rounds of consultation of Member States experts on Member State specific assumptions and draft modelling results. The responsibility for the results rests, however, with the authors of the scenario who were commissioned to do this work by Directorate General for Energy, Directorate General for Climate Action and Directorate General for Mobility and Transport.

This new update is based on the latest available statistical year from EUROSTAT at the time of the modelling (the year 2010). In comparison to the previous version, the newest macro-economic data already shows the statistical effects of the on-going EU's economic downturn in activity of different sectors as well as energy consumption and GHG emissions. The demographic and economic forecasts reflect recent projections by EUROSTAT and the joint work of the Economic Policy Committee and the European Commission (DG ECFIN) respectively. The "Ageing Report 2012"[2] has been the starting point of this ex-

[1] Please see: http://ec.europa.eu/energy/observatory/trends_2030/
[2] Please see: http://ec.europa.eu/economy_finance/publications/european_economy/2012/2012-ageing-report_en.htm.

The Reference scenario was elaborated by a consortium led by the National Technical University of Athens (E3MLab), using the PRIMES model for energy and CO_2 emission projections, the GAINS model for non-CO_2 emission projections and the GLOBIOM-G4M models for LULUCF emission and removal projections, supported by some more specialised models (e.g. GEM-E3 model that has been used for projections for the value added by branch of activity, PROMETHEUS model that has been deployed for projections of world energy prices and CAPRI model for agricultural activity projections). Please see more information about these specialised models in the section on total GHGs emissions. The scenarios are available for the EU and each of its 28 Member States simulating the energy balances and GHG emission trends for future years under current trends and policies as adopted in the Member States by spring 2012.

The PRIMES model is a modelling system that simulates a market equilibrium solution for energy supply and demand in the EU28 and its Member States. The model determines the equilibrium by finding the prices of each energy form such that the quantity producers find best to supply matches the quantity consumers wish to use. The market equilibrium is achieved for each time period and the simulation is dynamic over time. The model is behavioural but also represents in an explicit and detailed way the available energy demand and supply technologies and pollution abatement technologies. The system reflects considerations about market economics, industry structure, energy/environmental policies and regulation, which are conceived so as to influence market behaviour of energy system agents. The modular structure of PRIMES reflects a distribution of decision making among agents that act individually about their supply, demand, combined supply and demand, and prices. The market integrating part of PRIMES subsequently simulates market clearing.

In this exercise the more detailed PRIMES-TREMOVE transport model was also used to develop the transport projections; this model is now fully integrated with the main PRIMES model.

PRIMES is a general purpose energy model; it is conceived for designing projections to the future, scenario building and policy impact analysis. It covers a medium to long-term horizon. Its modular structure allows either for integrating model use or for partial use.

ercise giving long term population and GDP growth trends up to 2060 while the short and medium term GDP growth projections were taken from DG ECFIN.

The recent boom in shale gas development and exploration of unconventional oil reserves are increasing the fossil fuel reserve basis and thus changing the projections about the developments of international fuel prices. The fuel prices have been updated in the new scenario to take into account the recent developments.

Significant progress has been made towards the achievement of the targets set out in the EU Energy and Climate Package, and new legislative measures, most notably the Energy Efficiency Directive[3], have been adopted at EU level. Several changes have occurred at national levels as well.

This report focuses on trend projections understood in the sense of a Reference scenario. Similar to the Reference scenario latest update from 2009, this Reference scenario starts from the assumption that the legally binding GHG and RES targets for 2020 will be achieved and that the policies agreed at EU level by spring 2012 (notably on energy efficiency) as well as relevant adopted national policies will be implemented in the Member States. Following this approach the Reference scenario can help enlightening the debate on where currently adopted policies might lead the EU and whether further policy development, including for the longer term, would be needed. This Reference scenario can therefore also serve as benchmark or reference for assessing the impacts of envisaged policy initiatives at EU level in the areas of energy, transport and climate.

Some technology development forecasts have changed since the latest update in 2009 both in positive way: faster than expected development for solar PV technology and negative: slower than expected developments for CCS and remote off-shore wind technologies.

Furthermore, international events, such as the Fukushima nuclear accident of March 2011, have changed the perception related to nuclear power generation and tightened the security requirements for nuclear technologies.

In the context of climate change policies, specific Copenhagen/Cancun pledges for 2020 have been also set in other world regions, which have been considered in the world energy price modelling part of this exercise.

EU Reference scenario 2013

The new Reference scenario determines as core element the development of the EU energy system under current trends and adopted policies. It includes current trends on population and economic development including the latest 2010 statistics and takes into account the highly volatile energy import prices environment of recent years. It portrays economic decisions, which are driven by market forces and technology progress in the framework of concrete national and EU policies and measures adopted until spring 2012 and which are or will be implemented over the next years. The Reference 2013 scenario includes all binding targets set out in EU legislation regarding development of renewable energies and reductions of greenhouse gas (GHG) emissions, as well as the latest legislation promoting energy efficiency.

These assumptions together with the current statistical situation derived from the EUROSTAT energy balances represent the starting point for projections which are presented from 2015 onwards in 5 years' steps until 2050.

The Reference 2013 scenario benefited from the comments of Member States experts. Many comments and additional information communicated by the Member States were accommodated in revising the draft Reference scenario, while preserving a harmonised approach to EU energy system modelling.

The modelling has involved Member States experts at various stages starting from responses to a very detailed policy questionnaire and the Member States' comments on macro-economic and sectorial economic projections. As a second step, detailed transport

[3] For precise references to legislation, please see Table 2.

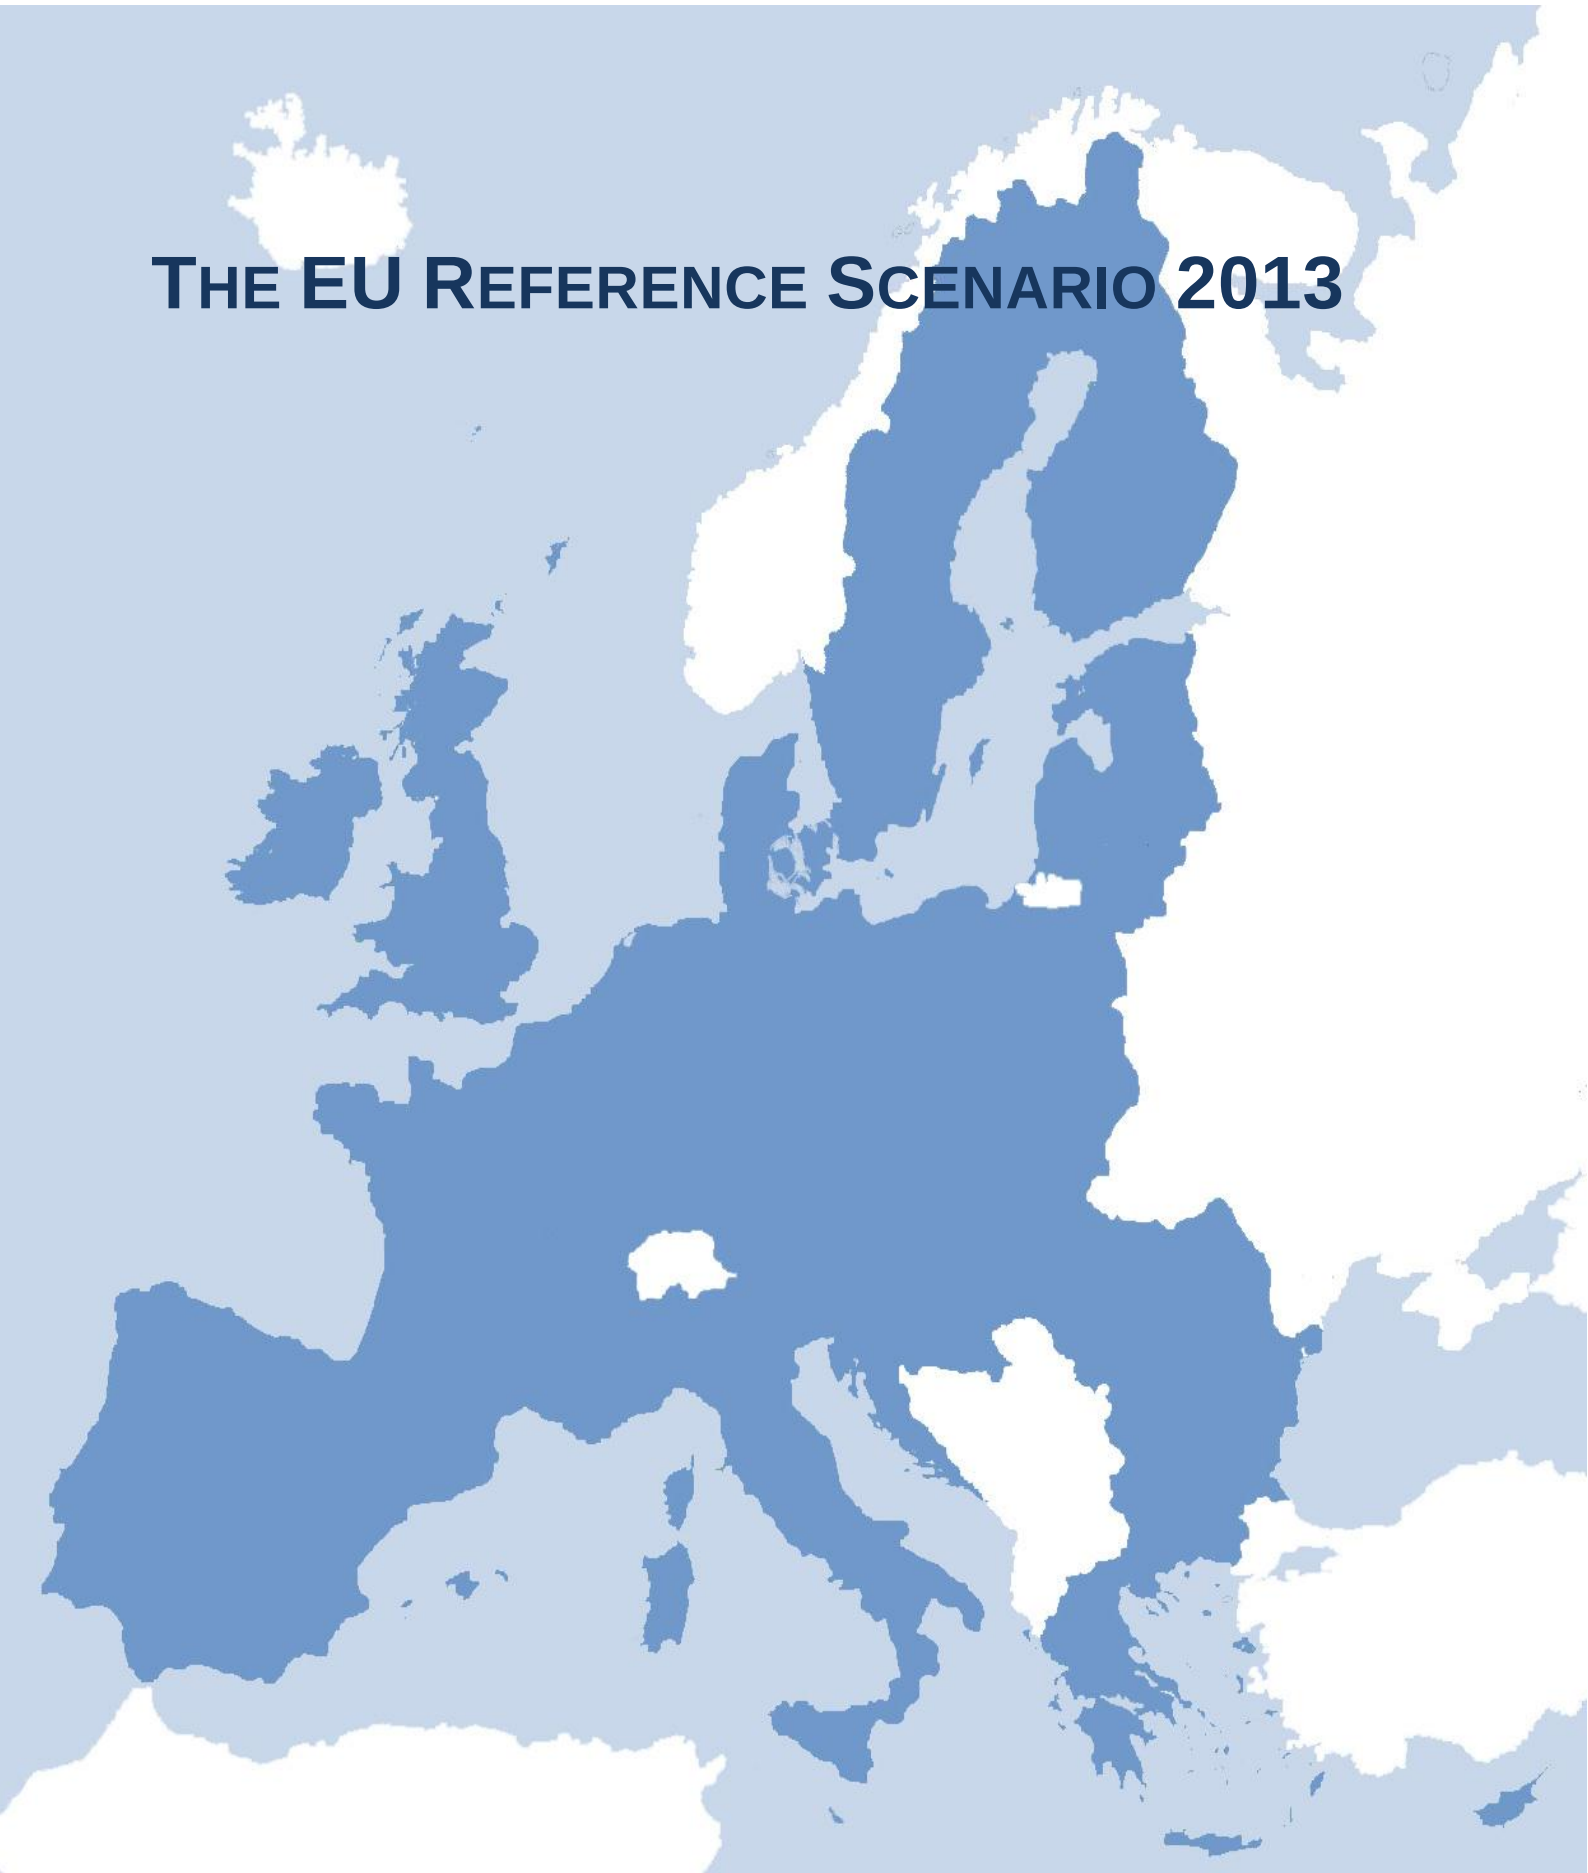
activity modelling took place on the basis of these consulted/revised economic trends, which, in turn, were consulted with Member States' experts in autumn 2012. The third modelling step consisted in energy system and economy modelling with PRIMES based on the revised economic and transport results from stages 1 and 2. The draft outcome of the energy modelling was again consulted with experts from the Member States. This step included also the modelling of energy related and industrial CO_2 emissions. The final step was the modelling and consultation of non-CO_2 GHG trends, including energy related ones, and of CO_2 emissions and removals related to land use, land use change and forestry (LULUCF). The macro-economic assumptions and the results of the energy modelling were important drivers for such GHG emissions, which were also based on modelling of other areas such as agriculture and forestry.

Member States comments have been accommodated as far as possible while striving to provide a consistent EU Reference scenario based on harmonised assumptions on e.g. GDP and world energy prices as well as EU and national policies and making sure that imports and exports of energy among Member States match. It needs to be, however, noted that the responsibility for these results lies with the consultants and the Commission services. In any case, the comments from Member States have helped a lot to improve the quality of the projections, on which this report gives an account, focusing on EU28 results.

In addition to its role as a trend projection, the Reference scenario is a benchmark for scenarios featuring alternative policy approaches or framework conditions (e.g. higher energy import prices, more ambitious renewables and climate policies).

All numbers included in this report, except otherwise stated, refer to European Union of 28 Member States.

THE EU REFERENCE SCENARIO 2013



2. Main assumptions

Macroeconomic and demographic scenario

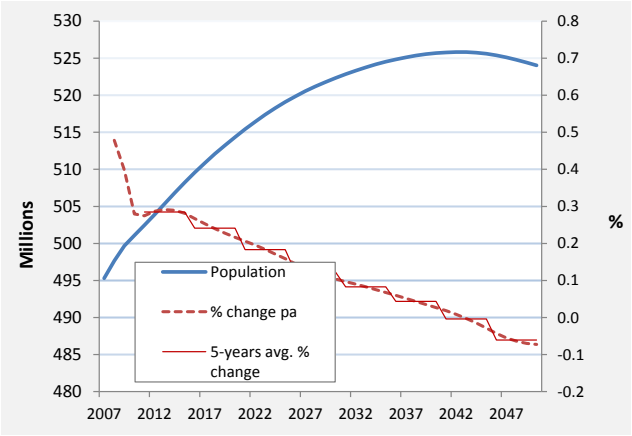
The Reference 2013 scenario builds on macro-economic projections of GDP and population which are exogenous to the models used. The historical time series from 1995 to 2010 were entirely updated using the time series from EUROSTAT. The economic indicators therefore fully reflect the economic downturn as it occurred in recent years up to 2010.

GDP and population projections by MS are considered as given. The scenario mirrors the recent DG ECFIN projections for the short and medium term (following the agreement reached in the Economic Policy Committee (EPC)) and the EPC/DG ECFIN Ageing Report 2012 (from first quarter 2012) for the long-run. The GEM-E3 model is used to project the structure of the economy and gross value added generated by different sectors, consistently with the given GDP projection.

The macroeconomic scenario comprises numerical projections of GDP (volume), households' income, population and sectorial activity (using gross value added in volume as a proxy) for 22 sectors, in each EU Member State. The 22 sectors comprise: 10 energy intensive industries, 6 non energy intensive industries, 3 service sectors, construction, agriculture and the energy supply sector (the value added of which is not used as input to the energy model given that it simulates the energy markets by considering all relevant drivers for energy demand and supply).

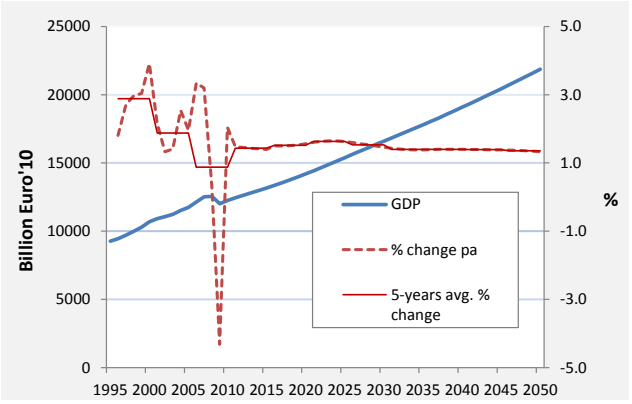
The population projections are based on EUROSTAT population projection for the period 2010 to 2050. This projection assumes fertility rates rising slightly, further life expectancy gains, and continued, but decelerating inward net migration to the EU. As a result, the EU population is projected to increase up to 2040 and decline slightly thereafter (see Figure 1). It is projected that the population undergoes significant changes in its age structure: the projections point to a significant reduction in the population aged 15-64 and an increase in persons aged 65 or more.

FIGURE 1: POPULATION OF EU28[4]



The GDP projection assumes a recovery from the current economic crisis, followed by steady GDP growth rates in the medium term (avg. 1.6% pa over the period 2015-2030, down from the 2.2% pa during 1996-2007), see Figure 2. In the longer term, lower growth rates are assumed (avg. 1.4% pa over the period 2030-2050). GDP/capita is projected to increase by a factor of 1.7 between 2010 and 2050. Labour supply is linked to slowly growing and then declining population as well as its ageing; this combined with assumptions on productivity trends from the Ageing report explain rather low potential GDP growth rates for the EU.

FIGURE 2: GDP OF THE EU27[5]



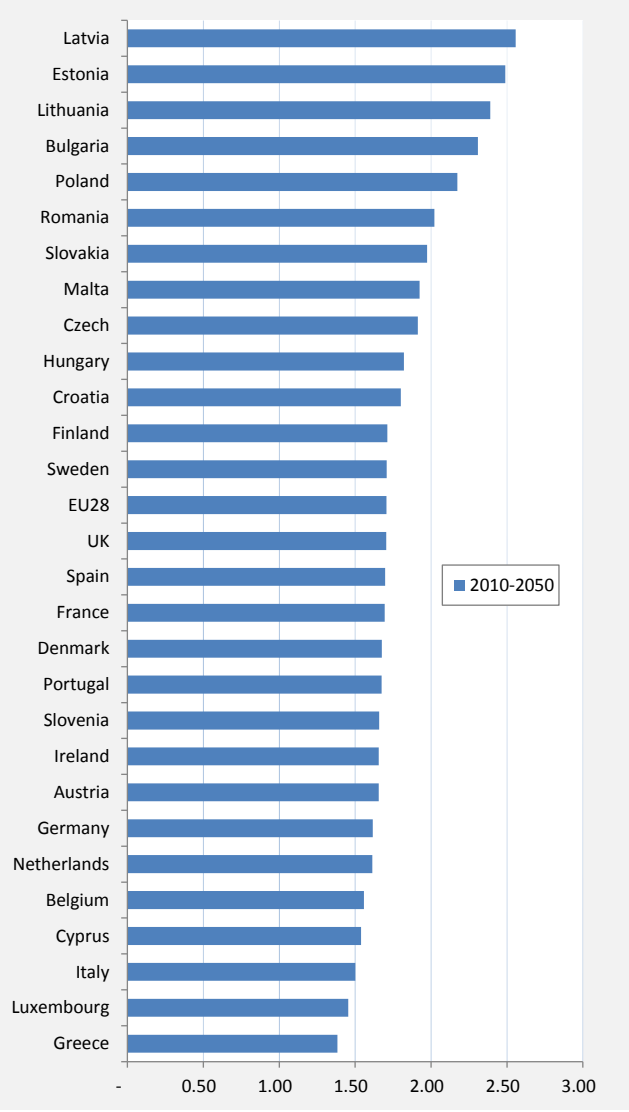
The highest GDP growth rate is projected in the period 2015-2030 whereas declining labour force and slowdown in productivity growth lead to lower growth

[4] Due to lack of consistent data for Croatia data is shown from 2007 onwards

[5] GDP is shown for the EU27 only as past consistent data for Croatia is only available from 2010 onwards.

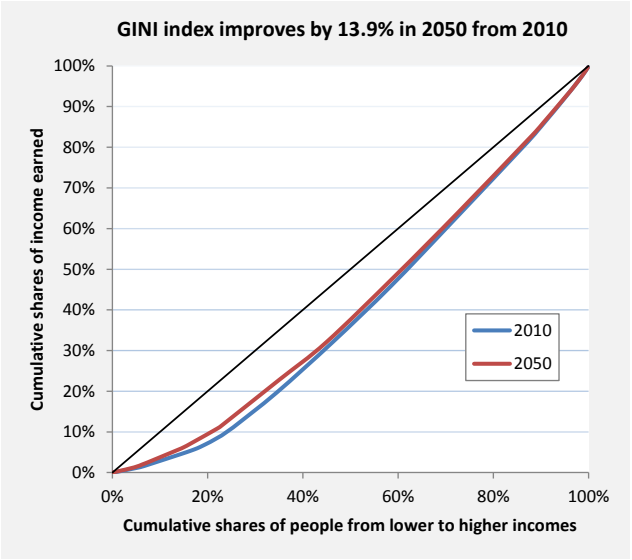
pace in the long term. Nevertheless, the slowdown in population growth allows for steady growth of GDP per capita in the long term. In this respect, the convergence is shown in the EPC/DG ECFIN Ageing Report 2012, which materialises through higher growth rates of the new Member States and, in the longer term, lower dispersion of GDP per capita among all the Member States (see Figure 3).

FIGURE 3: AVERAGE ANNUAL GROWTH RATE OF GDP PER CAPITA



The impact of the current debt crisis is significant in several EU countries, which will struggle to return to growth in the short term; on the other hand, several countries with lower GDP/capita are likely to see their relative position improved.

FIGURE 4: GINI INDEX FOR THE EU28 MEMBER STATES[6]



The Reference scenario projection sees a continuation of trends towards higher share of services in GDP, which generate 78% of total value added by 2050. The projection also shows a recovery of activity in industry after the current crisis with industry being projected to grow predominantly through shifting towards higher value added products, rather than higher amounts of products. For energy intensive industries recovery and then slow growth pace is projected. Non energy intensive industries see a more significant growth. The remaining sectors - construction, agriculture and energy sector - see a rather slow growth of activity.

- For basic metals (ferrous and non-ferrous) global projection shows steady growth of world consumption of basic metals, with very slow decoupling from world GDP growth. Faced with the global competition and demand growth mainly in other world regions, the EU's share in global market steadily declines, continuing past trends. Activity is, however, projected to remain in the EU, thanks to shifting production to high quality

[6] An improvement of the GINI coefficient by -13.9% means that in 2050 there is a better cohesion than in 2010 (lower inequality among incomes in MS). The main improvement of the GINI index comes from the lowest classes of income frequency distribution which means that poorer countries tend to grow faster than richer countries in the EU.
The calculation of the GINI coefficient includes Croatia.

products and to the tight links with equipment goods industry also located in the EU. EU production of pig iron and primary aluminium is projected to increase more slowly than growth of the basic metals industry, which include electric arc and recycled metals.

- For energy intensive chemicals, the recovery from crisis is slow and followed by slow growth. The EU production of fertilisers and petrochemical products is projected to stabilise and slightly decline in the long term as a result of weakening of EU competitiveness and low demand in the internal market. Other chemicals, particularly pharmaceutical and cosmetics, are projected to grow slightly faster.
- The non-metallic minerals sector – cement, ceramics, glass - is characterised by slow recovery from crisis followed by a slower growth pace than before the crisis. Slower growth is related to lower demand due to slowdown of construction activity linked to demographic change.
- For the paper and pulp industry there is significant recovery from crisis and sustained growth, although pulp production grows much less than the entire paper sector. Nonetheless there is a slow decline of EU share in global trade of paper and pulp.
- The equipment goods industry (engineering) is projected to remain the most dynamic sector in the EU industry, growing at steady pace, albeit slightly more slowly than in the period before the crisis.
- Other industries (food products, wood products, etc.) also see steady growth with the exception of textile industry, which is projected to decline, due to competition from other world regions.

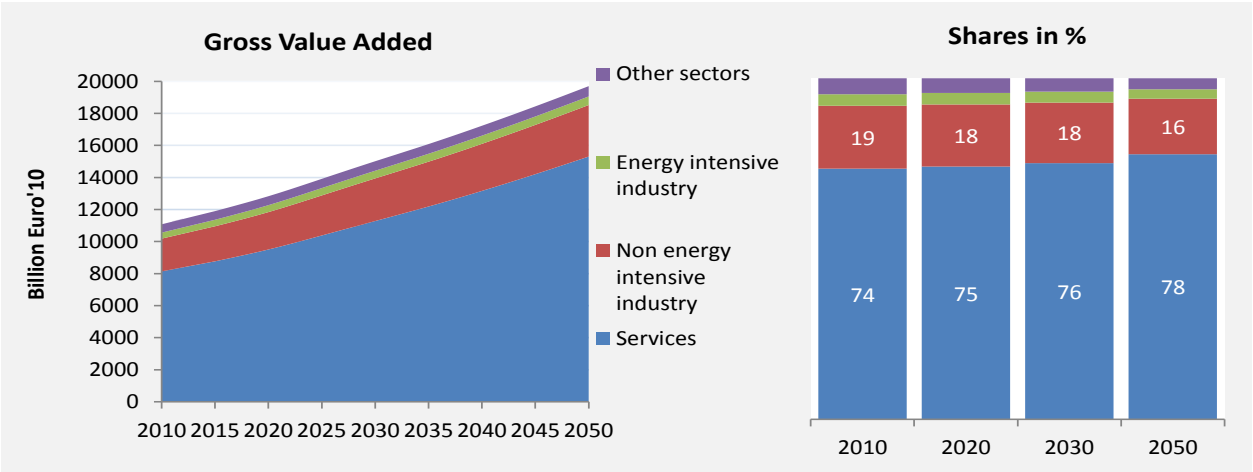
The macro-economic and sectorial projections are available by Member State (see Appendix 1).

World fossil fuel prices

The world fossil fuel price projections have undergone substantial revisions of key assumptions compared to the previous Reference scenario exercise: "Trends to 2030 – Update 2009" including on reserves notably of shale gas and other unconventional hydrocarbons, world economic developments and the reflection of Copenhagen/Cancun pledges. Prices are projected to develop along new trajectories rather different from the past ones, particularly for gas.

The projection has been developed independently with the PROMETHEUS model (stochastic world energy model) and was finalised in January 2012. The International Energy Agency World Energy Outlook (IEA WEO) for 2011 was published while work on the PROMETHEUS projections for the Reference scenario was already in progress, consequently an effort was made to harmonise some of the assumptions but otherwise the results have been arrived at inde-

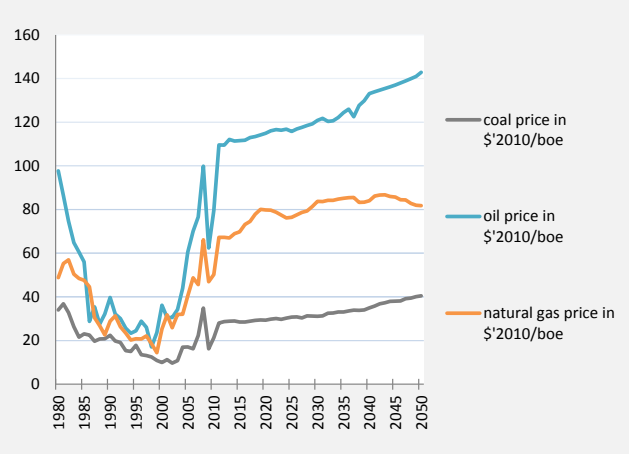
FIGURE 5: STRUCTURE OF THE ECONOMY IN EU28



pendently.

Large upward revisions for conventional gas and oil resources availability (following USGS, BGR, IEA) have been implemented as well as the inclusion of worldwide estimates of unconventional gas resources (tight sands, shale gas and coal bed methane) based on estimates from IEA. The change implies that the natural gas resource base increases more than 2.5 times with important implications on prices.

FIGURE 6: FOSSIL FUEL IMPORT PRICES



Regarding economic drivers, overall higher GDP growth is projected than in the previous exercise: major upward revisions were undertaken for China, India and Middle East and North Africa regions. For Europe DG ECFIN Ageing reports were used, whereas other regions basically follow IEA projections.

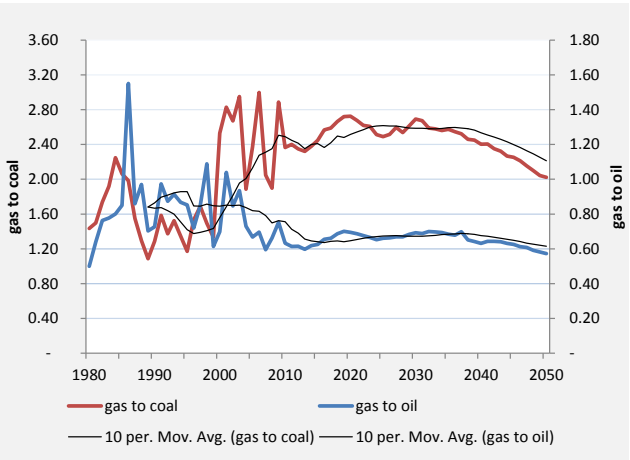
For the overall projection, the Copenhagen-Cancun pledges are expected to be respected through carbon prices as well as dedicated policies and measures. China, India and the CIS meet their pledges through "lack of ambition", whereas OECD Western Pacific fall considerably short because of high ambition compared to track record so far. Apart from the EU, no additional climate related policies are assumed for the period beyond 2030.

Up to 2035, the projections result in oil prices which are broadly in agreement with IEA-WEO 2011 and 2012 update (reporting up to that time horizon). For the shorter term, higher prices reflect failure of productive capacity to grow in line with demand (fuelled by economic recovery in the EU and US and persistent growth in emerging regions). The situation eases somewhat around 2020 before declining resource-production (RP) ratios result in resumption of upward trend in prices.

In the longer term, gas prices do not follow the upward trend of oil price. This is mostly due to the very large additional undiscovered resources that were factored in, including unconventional gas. More importantly, natural gas prices stabilise at a level that is still high enough to ensure economic viability of unconventional gas projects.

The downward revision of gas prices compared with the 2009 Baseline had also impacts on coal prices given that both fuels are competing in power generation.

FIGURE 7: RATIO OF GAS TO COAL AND GAS TO OIL PRICES



Energy technology progress

The EU Reference Scenario 2013, as the previous Reference scenarios, deals explicitly with the penetration of new technologies notably in power generation and transport and specifically with progress in renewable technologies including further technology learning. As analysed in the part on results, the penetration of new technologies leads to changes in the energy mix, alongside other drivers such as relative prices and costs, policies to promote energy efficiency, renewables and new technologies and broader market trends regarding economic efficiency and better use of resources. These interdependent developments also bring about energy efficiency improvements on both the demand and supply side. They also result in energy technology changes, which in the modelling are represented by an uptake of specific energy technologies from a broad portfolio of different technologies that change over time. The tech-

nology portfolio in the Reference Scenario includes the following categories:

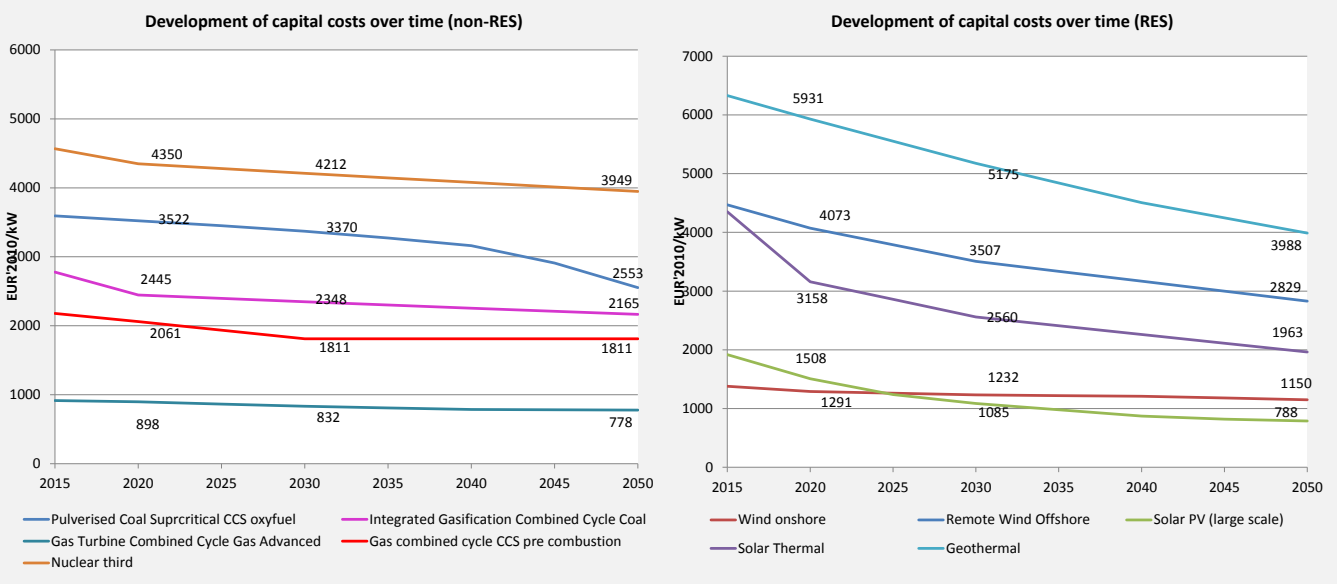
- End-use energy efficiency (thermal integrity of buildings, lighting, electric appliances, motor drives, heat pumps, etc.).
- Renewable energy in centralized and decentralized power generation, in direct heating and cooling applications, as well as for blending with petrol or diesel oil.
- Supercritical coal plants, advanced gas combined cycle plants and CHP.
- CO_2 carbon capture and storage (CCS).
- Nuclear energy including 3rd and 4th generation.
- Advanced transmission and distribution grids and smart metering.
- Plug-in hybrid and battery/full electric vehicles, both for passenger and freight road transportation (light commercial vehicles).
- Improvements in conventional engines in transport.

Although the key features of the technologies in the portfolio are known today, the projected evolution of their technical and economic characteristics presupposes that substantial industrial research and demonstration takes place enabling deployment at a wide scale.

Compared to the 2009 Reference exercise the development prospects of certain technologies have changed considerably and these have been taken into account in the PRIMES model. The changes include:

- Solar photovoltaics (PVs): techno-economic improvements in the solar PV industry have surpassed previous expectations and costs have changed already for the short term. The development of PVs starts from lower costs, than previously expected and has a positive learning curve throughout the projection period.
- Remote offshore wind: in the previous exercise, following the review of available literature assumptions, the assumptions about remote offshore wind were very positive, including strong cost reductions. Following the latest literature review, assumptions about techno-economic developments have been revised upwards. Capital costs for remote offshore wind developments are now expected to be significantly higher and the costs to reduce more slowly.
- Nuclear: since the Fukushima accident in March 2011 security standards for nuclear power plants have been tightened, leading to higher costs for their construction and testing requirements. Costs for nuclear power plants are therefore increased. With the new risk assessment, financing conditions for nuclear

FIGURE 8: DEVELOPMENT OF CAPITAL COSTS OVER TIME FOR POWER GENERATION TECHNOLOGIES



power plants have also worsened and this is also reflected in the modelling.

- CCS: the construction of power plants equipped with carbon capture technologies has been developing at a much slower pace than expected at the time of development of the 2009 Reference exercise. Development of CCS is also hampered and delayed due to public acceptance issues over building of the storage capacities. The new difficulties and the delays in the development of CCS are taken into account in this new exercise.
- Demand side technologies have been updated where is was found necessary following latest literature review which includes the most up to date preparatory studies for the preparation of eco-design regulations and the amendment of CO_2 from light duty vehicles regulation.

The modelling also assumes that learning curves apply for specific technologies, thus reflecting decreasing costs and increasing performances as a function of cumulative production. The steepness of the learning curve differs by technology, depending also on their current stage of maturity.

TABLE 1: EXAMPLES OF COSTS AND EFFICIENCIES OF DEMAND SIDE TECHNOLOGIES

Appliance/Equipment		Unit	Base case	Improved	Advanced	Best
Domestic Dishwashers	*Consumption*	*kWh/hour*	1.05	-5%	-10%	-20%
	Costs	*EUR'10/appl*	349	29%	80%	130%
Domestic Lighting	*Consumption*	*kWh/hour*	0.03	-26%	-80%	-82%
	Costs	*EUR'10/appl*	4	34%	130%	165%
Domestic AC (Electricity)	*Efficiency*	*COP*	2.50	21%	47%	52%
	Costs	*EUR'10/kW*	415.7	20%	61%	85%
Domestic boiler -Dwelling size (natural gas)	*Efficiency*	*(Useful/Final)*	0.68	9%	23%	30%
	Costs	*EUR'10*	3342	15%	49%	71%
Water heating boiler (natural gas)	*Efficiency*	*(Useful/Final)*	0.64	21%	42%	47%
	Costs	*EUR'10*	700	40%	101%	131%

For power generation technologies the Reference scenario takes an optimistic view about the future, without however assuming breakthroughs in technology development. All power technologies known today are projected to improve in terms of unit cost and efficiency.

Taking into account the technology portfolio available, energy efficiency gains in the scenarios are driven by microeconomic decisions, reflecting the market agents' aim of minimizing costs and maximizing economic benefits operating in the context of public policies that promote energy efficiency. Similarly, renewables and CHP development are driven by private economic considerations also taking into account supportive policies which are assumed to continue in the Reference scenario and gradually decrease in the longer term (see policy assumptions).

The techno-economic characteristics of existing and new energy technologies used in the demand and the supply sectors of the energy system evolve over time and improve according to exogenously specified trends including learning rates. At any given time, several technologies are competing with different performance and costs as presented by examples in Table 1. Following the logic developed in the previous PRIMES versions, consumers and suppliers are generally hesitant to adopt new technologies before they become sufficiently mature. They behave as if they perceive a higher cost (compared to engineering cost evaluations for the operation of such equipment) when deciding upon adoption of new technologies.

Public policies at EU and national level, through information campaigns, industrial policy, R&D support, taxation and other means, aim at pushing more rapid adoption of new technologies by removing or compensating uncertainties associated with their use. In this way, the technologies themselves reach maturity more rapidly as a result of "learning-by-doing" effects and economies of scale. Supportive policies for the adoption of new technologies thus lead to modifications in the perception of technologies.

In the end, agents adopt new technologies because they aim at reducing the costs of energy services, which represent an important household budget/company balance sheet item. On macro-economic

level, GDP growth is therefore associated with continuous improvement of the technological basis leading to improved energy intensity, which is also supported by the effects from structural change in the economy.

Last but not least, the deployment of some of the new technologies depends on the development of new infrastructure and regulations, which are partly driven by government. This is the case, for example, for interconnectors and grid expansion, CCS regarding the transportation and storage of captured CO_2 and for the electrification of transportation which depends on TSOs and DSOs undertaking grid and control systems investments.

Technology assumptions are based on extensive literature review by the PRIMES team and have additionally been checked by the Commission Services, notably the Joint Research Centre of the European Commission.

Policy assumptions

The Reference scenario 2013 includes policies and measures adopted in the Member States by April 2012 and policies, measures and legislative provisions (including on binding targets) adopted by or agreed in the first half of 2012 at EU level in such a way that there is almost no uncertainty with regard to their adoption. This concerns notably the Energy Efficiency Directive, on which political agreement was reached by that time. The policies and measures reflected in the Reference 2013 scenario are described in Table 2.

TABLE 2: EU AND OTHER POLICIES INCLUDED IN THE REFERENCE SCENARIO 2013

EU LEVEL POLICIES

	Energy Efficiency

Power generation and energy markets		
20	Cogeneration Directive	Directive 2004/8/EC
21	Completion of the internal energy market (including provisions of the 3rd package). Since March 2011, the Gas and Electricity Directives of the 3rd package for an internal EU gas and electricity market are transposed into national law by Members States and the three Regulations: - on conditions for access to the natural gas transmission networks - on conditions for access to the network for cross-border exchange of electricity - on the establishment of the Agency for the Cooperation of Energy Regulators (ACER) are applicable.	Directive 2009/73/EC Directive 2009/72/EC Regulation (EC) No 715/2009, Regulation (EC) No 714/2009 Regulation (EC) No 713/2009
22	Energy Taxation Directive	Directive 2003/96/EC
23	Regulation on security of gas supply	Regulation (EU) 994/2010
24	Regulation on market integrity and transparency (REMIT)	Regulation (EU) 1227/2011
25	Nuclear Safety Directive	Council Directive 2009/71/Euratom
26	Nuclear Waste Management Directive	Council Directive 2011/70/Euratom
27	Directive on the promotion of the use of energy from renewable sources ("RES Directive")	Directive 2009/28 EC

(Cross-sectoral) Climate policies		
28	EU ETS directive	Directive 2003/87/EC as amended by Directive 2004/101/EC, Directive 2008/101/EC and Directive 2009/29/EC and implementing Decisions, in particular 2010/384/EU, 2010/634/EU, 2011/389/EU (cap), 2011/278/EU, 2011/638/EU (benchmarking and carbon leakage list)
29	Directive on the geological storage of CO_2	Directive 2009/31/EC
30	GHG Effort Sharing Decision	Decision 406/2009/EC
31	F-gas Regulation	Regulation (EC) No 842/2006
Transport related policies		
32	Regulation on CO_2 from cars	Regulation (EC) No 443/2009
33	Regulation EURO 5 and 6	Regulation (EC) No 715/2007
34	Fuel Quality Directive	Directive 2009/30/EC
35	Regulation Euro VI for heavy duty vehicles	Regulation (EC) No 595/2009
36	Regulation on CO_2 from vans	Regulation (EU) No 510/2011
37	Eurovignette Directive on road infrastructure charging	Directive 2011/76/EU
38	Directive on the Promotion of Clean and Energy Efficient Road Transport Vehicles (in public procurement)	Directive 2009/33/EC
39	End of Life Vehicles Directive	Directive 2000/53/EC
40	Mobile Air Conditioning in motor vehicles Directive	Directive 2006/40/EC
41	Single European Sky II	COM(2008) 389 final
42	Directive on inland transport of dangerous goods	Directive 2008/68/EC
43	Third railway package	Directive 2007/58/EC
44	Directive establishing a single European railway area (Recast)	Directive 2012/34/EU
45	Port state control Directive	Directive 2009/16/EC
46	Regulation on common rules for access to the international road haulage market	Regulation (EC) No 1072/2009
47	Directive concerning social legislation relating to road transport activities	Directive 2009/5/EC
48	Regulation on ground-handling services at Union airports	Part of "Better airports package"[7]
49	Regulation on noise-related operating restrictions at Union airports	Part of "Better airports package"[8]
50	Directive on the sulphur content of marine fuels	Directive 2012/33/EU

NATIONAL MEASURES

66	Strong national RES policies	National policies on e.g. feed-in tariffs, quota systems, green certificates, subsidies, favourable tax regimes and other financial incentives are reflected.
67	National Energy Efficiency policies	National policies promoting energy efficiency implementing EU directives and policies, as well as specific national policies are fully taken into account
68	Nuclear	Nuclear, including the replacement of plants due for retirement, is modelled on its economic merit and in competition with other energy sources for power generation but also taking into account the national policies, including legislative provisions in some MS on nuclear phase out. Several constraints are therefore put on the model such as decisions of Member States not to use nuclear at all (Austria, Cyprus, Denmark, Estonia, Greece, Ireland, Italy, Latvia, Luxembourg, Malta and Portugal). The nuclear phase-out in Belgium and Germany is respected while lifetime of nuclear power plants was extended to 60 years in Sweden. Nuclear investments are possible in Bulgaria, the Czech Republic, France, Finland, Hungary, Lithuania, Poland, Romania, Slovakia, Slovenia and Spain. For modelling the following plans on new nuclear plants were taken into account: Finland (1720 MW by 2015), France (1600 MW by 2020), Lithuania (1400 by 2025), Poland (1600 MW by 2025), Slovakia (940 MW by 2015). Member States experts were invited to provide information on new nuclear investments/programmes in spring 2012 and comments on the PRIMES Reference scenario results in winter 2013, which had a significant impact on the modelling results for nuclear capacity.

OTHER SUPRA-NATIONAL LEVEL POLICIES

69	Energy Star Program (voluntary labelling program)	
70	International Maritime Organisation (IMO) International convention for the prevention of pollution from ships (MARPOL), Annex VI	2008 amendments - revised Annex VI (Prevention of Air Pollution from ships)
71	WTO Agreement on trade with agricultural products from Uruguay round fully respected	
72	Voluntary agreement to reduce PFC (perfluorocarbons, potent GHG) emissions in the semiconductor industry	
73	International Civil Aviation Organisation (ICAO), Convention on International Civil Aviation, Annex 16, Volume II (Aircraft engine emissions)	
74	IMO, Inclusion of regulations on energy efficiency for ships in MARPOL Annex VI	IMO Resolution MEPC.203(62)

Further assumptions

Discount Rates

The PRIMES model is based on individual decision making of agents demanding or supplying energy and on price-driven interactions in markets. The modelling approach is not taking the perspective of a social planner and does not follow an overall least cost optimization of the entire energy system in the long-term. Therefore, social discount rates play no role in determining model solutions. Social discount rates can however be used for ex post cost evaluations.

On the other hand discount rates pertaining to individual agents play an important role in their decision-making. Agents' economic decisions are usually based on the concept of cost of capital, which is, depending on the sector, either weighted average cost of capital (for larger firms) or subjective discount rate (for individuals or smaller firms). In both cases, the rate used to discount future costs and revenues involves a risk premium which reflects business practices, various risk factors or even the perceived cost of lending. The discount rate for individuals also reflects an element of risk averseness.

The discount rates vary across sectors and may differ substantially from social discount rates (typically 4-5%) which are used in social long-term planning. In the PRIMES modelling, the discount rates range from 8% (in real terms) applicable to public transport companies or regulated investments as for example grid development investments (in the form of weighed average cost of capital) up to 17.5% applicable to individuals (households and private passenger transport, following extensive literature review on discount rates of private consumers). Additional risk premium rates are applied for some new technologies at their early stages of development impacting on perceived costs of technologies.

More specifically, for large power and steam generation companies the cost of capital are 9%. In industry, services and agriculture the discount rate amounts to 12%. Households have an even higher discount rate of 17.5%. For transport, the discount rate depends on the type of operator. Private passenger transport investments (e.g. for cars) are based on a discount rate of 17.5%, while for trucks and inland navigation ships, which are considered as investment goods the rate is 12%. Public transport investment is simulated with an assumed discount rate of 8% for the whole projection period reflecting the acceptance of longer pay-back periods than those required in industry or private households. All these rates are in real terms, i.e. after deducting inflation.

The decision-making environment of businesses and households on energy consumption is expected to change because of the implementation of the Energy Efficiency directive (EED). The EED will bring about higher market penetration of Energy Service Compa-

nies (ESCOs) or similar institutions as well as the reduction of associated risks as perceived by potential clients through quality controls and certifications. This will entail lower perceived discount rates and is reflected in the new Reference scenario. The implementation of the EED and the widespread penetration of ESCOs is mirrored by the reduction of discount rates by up to 2 percentage points in services and up to 5.5 percentage points in households. Discount rates are assumed to decline linearly from their standard levels in 2010 to reach the policy driven values by 2020 and they remain at these levels throughout the remaining projection period. Thus the discount rates for households are reduced in the context of the Reference scenario to 14.75% in 2015 and 12% from 2020 onwards throughout the entire projection period. For services the discount rate was progressively decreased to 11% in 2015 and 10% from 2020 onwards (see Figure 9).

FIGURE 9: DISCOUNT RATES USED IN PRIMES

Discount rates (in real terms)	Standard discount rates of PRIMES	Modified discount rates due to EED	
		2015	2020 - 2050
Power generation	9%	9%	9%
Industry	12%	12%	12%
Tertiary	12%	11%	10%
Public transport	8%	8%	8%
Trucks and inland navigation	12%	12%	12%
Private cars	17.5%	17.5%	17.5%
Households	17.5%	14.75%	12%

Degree days

The degree days, reflecting climate conditions, are kept constant at the 2005 level, which is higher than the long term average without assuming any trend towards further warming. The degree days in 2000 were fairly similar to the ones in 2005. The year 2010 was not considered to be representative in terms of degree days. Such an approach facilitates comparison of statistics with the projection figures that are based on climate conditions at the beginning of this century. This simplification can be also justified by consistency reasons given the status of model development. A selective inclusion of global warming trends only for some modelling parts where this would be feasible (heating degree days) and not for others (e.g. water supply conditions for power generation, impacts on agriculture) could lead to misleading results. Further research and modelling work is needed for an inclusion into a reference scenario.

Exchange rates

All monetary values are expressed in constant prices of 2010 (without inflation). The dollar exchange rate for current money changes over time; it starts at the value of 1.39$/€ in 2009 and is assumed to decrease to 1.30 $/€ by 2012, at which level it is assumed to remain for the remaining projection period.

3. Results for the EU Reference scenario 2013

The Reference 2013 scenario reflects current trends in developments in the EU energy system and in the global energy supply and demand, as described in detail in section 2, as well as the consequences of adopted policies presented in the Table 2. In this section, the main effects of these trends and of the implementation of policies listed above are presented, notably on energy demand, power generation and emissions developments for the EU28.

The projections were performed by the PRIMES model and its satellite models: PRIMES-TREMOVE transport model and PRIMES biomass supply model. The horizon of the projection is 2050 and results are available in five-year time steps, for each Member State and for the EU28.[10]

Considering the timeframes of the policies included in the Reference 2013 scenario, the results are presented distinguishing between three time periods, up to 2020, 2020-30 and 2030-50. Up to 2020 the main driver of developments is the achievement of the targets of the 20-20-20 Climate and Energy Package and the EED. This period is characterised by increased penetration of RES and by strong energy efficiency improvements. In parallel, until 2020, increasing international fossil fuel prices have considerable implications on energy demand. Moreover, the reader should keep in mind that the period 2010-2015 is characterised by increased growth rates in energy demand, as the economy is projected to be recovering from the recent economic crisis (see the macro-economic data in Appendix 1).

In the decade 2020-30, the Reference scenario 2013 does not incorporate further targets with regard to RES, but market dynamics, the on-going enabling policies (such as streamlined authorisation procedures) and technology cost reductions allow for further penetration, albeit at lower growth rates. Also energy efficiency measures implemented up to 2020 continue to deliver improvements in this period (as the lifetime of new appliances, renovated buildings etc. extends beyond the lifetime of the policies). As with renewables, the improvement rates slow-down in the absence of specific new policy measures. International fossil fuel prices are high but more stable in comparison to the previous decade.

The ETS Directive continues to influence the energy system, as the number of EU-ETS emissions allowances, continues decreasing linearly at 1.74% p.a. as specified in the directive. This drives strong emission reductions in particular in the power generation sector, including in the longer term – up to 2050.

Overview of the implications of energy efficiency policies and measures

The Reference 2013 scenario reflects all the policies that have been adopted in recent years regarding energy efficiency in the EU and in MS, including the Energy Efficiency Directive (EED) (see Table 2). In the following, we discuss these measures and provide a general overview of their effects on the energy system, as well as their reflection in the PRIMES model.

First of all, the EED (via its energy savings obligation) and the Energy Performance of Buildings Directive (EPBD) provisions bring about energy efficiency improvements in buildings through energy-related renovations of the existing building stock as well as improvements of the energy performance characteristics in new constructions. Renovations lead to better insulation of the buildings (e.g. through window replacement, better façade insulation, roof insulation) or changes in heating devices, resulting therefore in energy savings at a building level. After 2020, further energy savings are induced as new households are built following regional passive house standards.

Regarding heating systems, in the context of the Reference 2013 scenario, the replacement of equipment is accelerated, as the energy efficiency measures incorporated induce a more rapid uptake of advanced technologies, whereas in the absence of such energy efficiency measures, replacement with new, more efficient technologies would occur only at the normal end of lifetime of the heating equipment. Energy efficiency improvements in heating systems are accelerated further through synergies of the different efficiency measures, such as increased technology

[10] Summary results for EU28 and for each country are presented in the Appendix.

transparency (labelling), efficiency standards (eco-design), highly efficient technical building systems (EPBD), professional support through energy service companies (ESCOs) and energy efficiency obligations on energy distributors and/or retail sellers which are therefore obliged to achieve significant energy savings at their customer sites, etc. The same efficiency improvements apply for cooling/ventilation, water heating and lighting.

The PRIMES model can simulate different energy efficiency policies with different modelling techniques. The model-specific instruments used affect the context and conditions under which individuals, in the modelling represented by stylized agents per sector, make their decisions on energy consumption and the related equipment.

An example of such modelling instruments is the modification of model parameters in order to mirror technology performance or the effects of building codes that are determined jointly in the process of calibrating the interdependent model output to the observations from the relevant statistical year (in this exercise: 2010). Another technique is modification of assumptions about technical and economic performance of future technologies that are available for future choices by consumers within the model projection.

Furthermore, there are specific modelling instruments for capturing the effects of measures that promote or impose efficiency performance standards (BAT, eco-design) and become increasingly important over time as new items penetrate the market while old items are getting out of use. Such modelling instruments relate to individual technologies or groups of technologies and modify the perception of associated costs by the modelled agents or influence the portfolio of technologies that will be available for consumer choice. Another type of measures are those which improve consumer information through education, labelling, correct metering and billing, energy audits and technology support schemes aiming at inciting consumers to select more efficient technologies. Such measures are dealt with through the modelling instruments discussed in this section or are directly reflected in the modelling mechanisms, where economic agents are per se informed correctly about the prevailing and to some extent future prices., depending on the sector (there is less foresight in final demand sectors with shorter equipment lifetimes than in power generation).

The energy efficiency policies mentioned above modify modelling parameters. This applies for example for the factors that affect perception of net energy costs (investment costs minus perceived benefits) including risk factors (e.g. risk related to maintenance costs or technical reliability of advanced technologies if chosen prior to fully established commercial maturity of such technologies). Such changes influence in turn the mix of different technologies delivering the same type of energy services. As in reality, the modelling reflects the existence of mixes of technologies and appliances for the same purpose with different energy consumption and other characteristics, for which economic actors have different perceptions regarding costs. The factors affecting perception of costs vary by equipment type. The efficiency policy induced changes in the Reference scenario for household appliances lead to perceived cost decreases in the more advanced technology options of between 12 and 20% compared to the costs that would have been perceived in the absence of the energy efficiency policies.

The penetration of ESCOs as explicitly incited by the EED leads to an environment with reduced risks for the consumers engaging in energy efficiency renovations, which can include both changes in the building structure and changes in the energy equipment. This is represented in the modelling by reduced discount rates for certain sectors, mirroring the changes in the decision making conditions and constraints of e.g. households and services. Consequently, the (high) subjective discount rates which prevail in capital-budgeting decisions when such decisions are taken solely by individuals, facing high information costs, are reduced, moving closer to business interest rates. In fact, the involvement of ESCO and the obligation for energy distributors and retail sellers to facilitate energy efficiency investment at the premises of final customers enable individuals to make more cost-

effective choices thanks to the professional support of e.g. ESCOs and utilities that are obliged to achieve energy savings with their customers. In this way lower discount rates reduce the high weight that initial investment costs have compared with future energy cost savings. In addition, these measures also induce lower technical and financial risk, hence reducing the perceived costs of new technologies and saving investments, (see also point above on perception of costs). The discount rates used for the Reference scenario 2013 are reported in the introductory section.

Another key modelling tool are efficiency values (EVs) reflecting a variety of broad and sometimes unspecified instruments that bring about efficiency improvements. In the most concrete form these values represent the price of hypothetical White Certificates, reflecting the marginal costs of reaching energy savings obligations, e.g. for energy distributors and retail sellers regarding energy efficiency at final customers sites. In the Reference scenario, these values represent the implementation of the EED energy savings obligations in domestic and service sectors, specific building renovation policy efforts or a large range of other pertinent measures, such as energy audits, energy management systems, good energy advice to consumers on the various benefits of energy efficiency investment and better practices, targeted energy efficiency education, significant voluntary agreements, etc.

In modelling terms therefore, the PRIMES model includes a number of instruments to reflect policies leading to efficiency improvements.

The EED includes specific public procurement provisions which translate into a 3% p.a. refurbishment rate in the modelling and induce multiplier effects, as the public sector assumes an exemplary role, i.e. private consumers are imitating the public sector energy efficiency actions. Moreover, energy efficiency obligations on energy distributors and retail sellers, as well as alternative policy measures (e.g. financing, fiscal, voluntary, and information measures) required by MS according to the EED, drive further investment choices in improving thermal integrity of houses and buildings, as well as the introduction of more efficient appliances and better management of existing equipment in final energy use sectors. For the modelling of the energy savings obligation or alternative measures it has been assumed that the possible exemptions for ETS installations and transport are used.

Energy efficiency improvements also occur on the energy supply side, through the promotion of investments in CHP and in distributed steam and heat networks. These investments are combined with incentives on the consumer side to shift towards heating through district heating, both in the residential and the tertiary sectors[11].

Improvements in the network tariff system and the regulations regarding the design and operation of gas and electricity infrastructure are also required in the context of the EED; moreover, the EED requires MS and regulators to encourage and promote participation of demand side response in wholesale and retail markets. In this context, the Reference 2013 scenario assumes that intelligent metering is gradually introduced in the electricity system, enabling consumers to more actively manage their energy use. This allows for demand responses so as to decrease peak and over-charging situations, which generally imply higher losses in the power grids. Thus, efficiency is also improved as a result of the intelligent operation of the systems.

Finally, some policies and measures that do not target energy efficiency directly, but for example target emissions reduction, lead to significant additional energy efficiency benefits. Among these policies are the ETS Directive (for details see section on ETS below), the Effort Sharing Decision (ESD), and the CO_2 standards for cars and vans. These policies drive energy efficiency improvements along with fuel switching as a means of achieving reduction of emissions. The ESD defines legally binding national GHG emission targets in 2020 compared with 2005 for sectors

[11] This incurs some rebound effects, e.g. houses connected to district heating generally consume more heat than houses which use individual (non-central) heating equipment, as district heating is more cost efficient; such features are automatically integrated in this price responsive energy modelling

not covered by the EU ETS, ranging between -20% and +20%, which shall lead to a EU-wide emission reduction by 10%. To achieve the targets, it also defines for each country a linear emission path between 2013 and 2020 which has to be satisfied each year but is subject to a number of important flexibility mechanisms, e.g. a carry-forward of emission allocations, transfers between Member States and use of international credits. It turned out that for the EU as a whole the -10% target is achieved without the need for modelling additional specific policy incentives. With regard to the national target trajectories, in general, flexibility both over time and between Member States via the use of transfers has been assumed to reflect the use of economically effective options to meet the targets while respecting the clear Member State indications on flexibility limitations[12].

For the CO_2 standards for cars and vans, it is assumed, based on current reduction trends, that the 2020 CO_2 targets for new vehicles set out in the regulations are achieved and remain constant afterwards (for cars 95gCO_2/km, for vans 147gCO_2/km).

Policies on promoting RES also indirectly lead to energy efficiency gains; in statistical terms many RES, such as hydro, wind and solar PV, have an efficiency factor of 1; thus, the penetration of RES in all sectors, in particular in power generation, induces energy savings. Other measures that foster energy efficiency are financial instruments, in particular excise type taxes (including those reflecting emissions); they are directly modelled in PRIMES allowing for the full reflection of the effects of energy taxation and other financial instruments on end user prices and energy consumption.

Overall, the energy savings achieved in the Reference 2013 scenario in 2020 amount to 16.8% (Table 3) using the metric defined for the 20% energy savings target. This figure is obtained through comparison with the primary energy consumption (defined as gross inland consumption minus non-energy use) projections of the Baseline 2007 scenario, which has been used as the base for the energy savings objective of the 20-20-20 climate and energy package. The projected decrease reflects the aggregate effect on energy consumption of all the policies that are included in the Reference 2013 scenario.

TABLE 3: EFFECT OF POLICIES ADOPTED IN THE REFERENCE 2013 SCENARIO ON ENERGY CONSUMPTION[13]

	2020	2030	2050
Primary energy consumption - % change from Baseline 2007*	-16.8%	-21.0%	
Primary energy consumption - % change from Reference 2011	-2.5%	-1.3%	1.2%
Gross inland consumption - % change from 2005**	-9.2%	-12.1%	-11.1%
Primary energy consumption - % change from 2005	-9.9%	-13.0%	-11.8%

* Time horizon of Baseline 2007 scenario was year 2030

** Year 2005 was the peak year for energy consumption in the EU

General overview of RES supporting measures and the evolution of RES indicators

The Reference 2013 scenario starts from the assumption that the EU energy system evolves so that the legally binding targets on RES (20% share of gross final energy consumption from RES by 2020 and 10% specifically in the transport sector) are achieved. In parallel, the framework for the penetration of RES significantly improves in the projection, as the Reference 2013 scenario incorporates known direct RES aids (e.g. feed-in tariffs) and other RES enabling policies, such as priority access, grid development and streamlined authorisation procedures. Obviously, RES penetration is also facilitated by the ETS (depending on carbon prices).

As indicated in the Member States' submissions to the EC, the national RES 2020 targets are generally expected to be achieved at the Member State level, including only very limited recourse to the co-operation mechanism for those few countries that have not excluded making use of it. Drawing on current Member States plans to meet their legal obligations, the Reference 2013 scenario takes into account the Member States projections on the trajectories of the RES shares by sector (RES-H&C for heat-

[12] Given the projected EU-wide compliance, it has been assumed that transfers between Member States will be available at very low prices just covering administrative costs, making it economically unattractive to resort to the permitted use of international credits. The relatively small costs and benefits of these emission transfers have been included in the total system costs for 2020.

[13] Primary energy consumption is defined as gross inland consumption minus non-energy use.

ing and cooling, RES-T for transport and RES-E for electricity) as expressed in the respective National Renewable Energy Action Plans (NREAPs).

The PRIMES model has included detailed modelling of Member State policies representing a variety of economic support schemes, including feed-in-tariffs. A survey has been conducted for the purpose of the Reference 2013 scenario to correctly represent current incentive schemes by Member State, including their budget limitations when these exist. The existing incentives have been then extrapolated to 2020 (if the Member State does not include provisions up to 2020) in a conservative manner. The RES investments resulting from the overall policy and economic context as well as incentives have been projected assuming that investors evaluate project specific Internal Rates of Return including the financial incentives and decide upon investing accordingly. The projected RES investments implied directly for the financial incentives are considered as given by the market model which decides upon the remaining potentially necessary investments (among all power generation technologies) based on pure economic considerations with a view to meeting the RES obligations.

Special fuel and electricity price elements (fees) are accounted for in the model to recover fully all the costs for the RES which are calculated through the incentives and the contracting obligations over time. The model further keeps track of the RES technology vintages as projected and the outstanding fee is raised throughout the economic lifetime of the thus built power capacity, therefore also beyond 2020. For Member States which do not achieve their RES target through direct incentive policies, an additional instrument is included in the modelling the so-called RES-value which is a dual variable for RES - introduced to meet the targets by Member State. The value represents yet unknown policies to provide incentives for RES such as further legislative facilitations, easier site availability or grid access, or even direct financial incentives, etc. The costs related to investments induced through the RES-value are fully recovered through electricity prices.

Overall, at the EU level, the RES share in gross final energy consumption in 2020 reaches 20.9% (Figure 10).

Beyond 2020, no additional RES targets are set. However, RES enabling policies, the ETS and some direct aids (depending on technologies and Member State) continue; the direct aids are assumed to phase out at a pace depending on RES technology. These assumptions - in combination with technology progress (capital cost reduction due to learning effects) - lead to further increase in RES penetration. In power generation particularly, the continuation of the ETS has a significant effect; until 2030, the share of RES in power generation reaches 43%, and 50% by 2050. In transport the increasing RES share is due to further penetration of biofuels and moderate electrification. Overall, RES in gross final energy consumption account for 24% and 29% in 2030 and 2050 respectively.

Although direct incentives are phased out, in power generation the investments in RES continue beyond 2020 due to three main factors: (1) continued learning by doing of technologies including continued RDI especially for innovative RES, (2) the ETS price and (3) extensions in the grid and improvement in market-based balancing of RES as well as streamlined authorization and priority access. The feed-in tariffs and other country specific financial incentives are assumed to be phased out beyond 2020 with the exception of incentives for innovative technologies such as tidal, geothermal, solar thermal, solar PV and remote off-shore wind where the phase out is more gradual. As to the RES-values, they steeply decrease beyond 2020, in the absence of specific RES obligations after 2020; therefore RES investments beyond 2020 are mainly driven by ETS carbon prices and are facilitated by non-financial supporting policies.

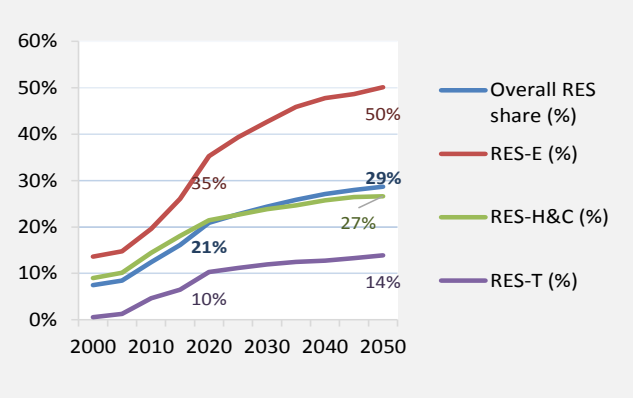
The learning by doing of RES technologies continues throughout the projection period and allows for some of the RES technologies to become economically competitive already after 2020.

The ETS prices, which rise considerably towards the end of the projection period (see next section), act as an incentive and as the model simulates perfect foresight, the investments are spread throughout the projection period.

A further important element concerns the changes in the electricity transmission system and the power market. Through the improvements in the grid and the Ten Years Network Development Plan of ENTSO-E the grid is better suited for up-taking higher shares of RES. Furthermore, it is assumed in the PRIMES modelling that the management of flows due to the implementation of the internal market changes. The EU target model is assumed to be successfully implemented. The Reference scenario modelling includes flow based allocation of interconnection capacities, assuming a market model purely basing trade on market forces throughout the EU internal energy market with perfectly operating market coupling across all participating countries. This market is assumed to operate successfully mainly beyond 2020. It implies that the balancing of RES occurs in a very cooperative and cost-efficient manner avoiding excessive investments in peak devices that would be resulting if national perspectives in balancing were persisting. Therefore the market improvements and the EU-wide market coupling allows for rather low balancing costs for RES, thus easing their market penetration.

Due to these changes in the system, the projected penetration of RES in power generation continues beyond 2020, albeit at a decelerated pace compared to the time period before 2020, and allows the share of RES in electricity (RES-E) to reach 50% by 2050.

FIGURE 10: RES INDICATORS AT THE EU LEVEL[14]



[14] Figures calculated according to the provision of RES Directive.

Overview of the EU ETS and projections on carbon prices

The EU ETS is modelled in its amended scope (third trading period from 2013 onwards), including also aviation, further industrial process emissions and certain industrial non-CO_2 GHGs. The latter are integrated based on results of GAINS non-CO_2 modelling (see section on non-CO_2 emission results) and PRIMES then ensures consistent modelling of the complete ETS. The annual volume of available EU ETS allowances (quoted as allowances hereafter) following the Directive provisions on the emissions cap, is assumed to decrease by 1.74% p.a. from 2013 throughout the projection period, except for aviation for which the cap remains stable from 2013 onwards at 95% of average 2004-6 emission levels. Aviation is modelled in the scope covered by EUROSTAT and therefore PRIMES based on fuels sold in the EU, which corresponds to domestic and outgoing international flights only.

International credits, priced at very low levels, are expected to be used in the period until 2020, and reaching the maximum permissible amount, preliminarily estimated for the modelling as around 1750 Mt CO_2 cumulatively.

The assumed cumulative emission cap 2008 to 2050 including the permissible international credits is around 69500 Mt. The different allowance allocation rules (auctioning, free allowances based on benchmarks) for the different sectors foreseen in the legislation, and including the provisions for sectors at risk of carbon leakage, are reflected in the modelling.

ETS prices are endogenously derived so as the cumulative ETS cap is met; the continuously decreasing number of available allowances combined with the significant allowance surplus which is only projected to decrease after 2020 (see below) suggest that the ETS price will follow only a slowly increasing trend until 2025 and stronger increases thereafter; it is projected to reach 10€'10/tCO_2 in 2020, 35€'10/tCO_2 in 2030 and 100€'10/tCO_2 in 2050 (Figure 11). The PRIMES model simulates emission reductions in ETS sectors as a response to current and future ETS prices (Figure 12), taking into account risk-averse behav-

ior of market agents which leads to banking of allowances; perfect foresight of the carbon price progression in the period 2020-50 and that no borrowing from the future is permitted. Increasing ETS prices induce a switch in power generation towards the use of low and zero carbon fuels or technologies (e.g. RES and CCS). Moreover, the increase in the cost of energy, reflecting the increasing ETS prices, supports energy efficiency and fuel switching in the ETS sectors. Finally, increasing ETS prices indirectly influence energy efficiency in demand side sectors as well, since expenditures for ETS allowances are passed through to consumer prices, notably in electricity prices.

With the current and projected low level of the ETS prices, the ETS emissions target for 2020 is achieved as there is also a large amount of additional policies implemented, particularly RES support policies but also the EED, which influence also the ETS sectors, and because the economic crisis substantially reduced the industrial production as well as power demand and thus GHG emissions. The projection of ETS prices is based on the assumptions that actors are risk-averse and have strong trust in the continuation of the ETS legislation; should this not to be the case, ETS prices would drop considerably below the projected levels in the short term.

In the longer term, the trend of very low carbon prices is reversed; beginning in 2030 and throughout the period to 2050, the level of the ETS price is increasing significantly. This is the consequence of decreasing allowances supply following the implementation of the linear reduction factor that reduces the cap substantially over time and a combination of energy supply factors, namely of the delayed technology developments of CCS, public acceptance problems with nuclear energy and CO_2 storage, the updated offshore wind cost assumptions and phasing out of RES support as well as the trends in world fuel prices, where a decoupling of oil and gas prices takes place, with gas prices remaining in the longer term at relatively stable levels.

FIGURE 11: PROJECTION OF THE ETS PRICE

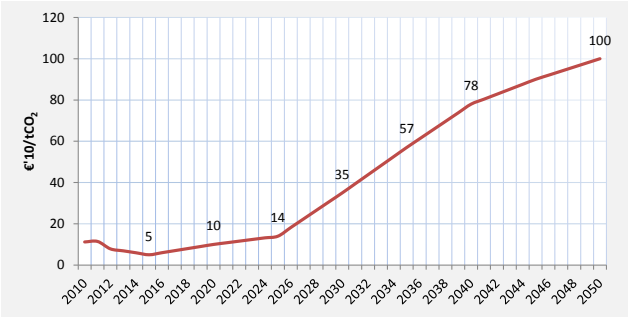


FIGURE 12: AVAILABLE ALLOWANCES[15] AND ETS GHG EMISSIONS PROJECTION

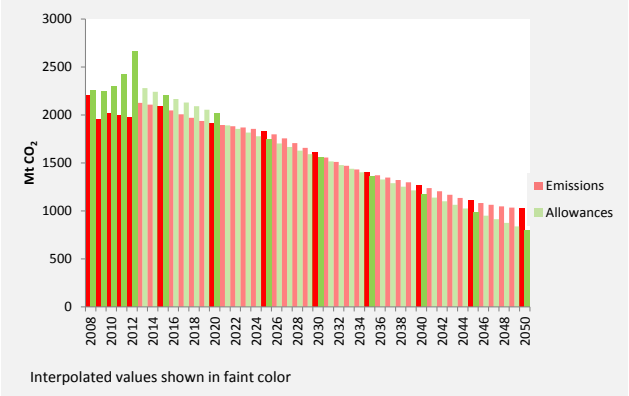

FIGURE 13: PROJECTION OF ALLOWANCES SURPLUS

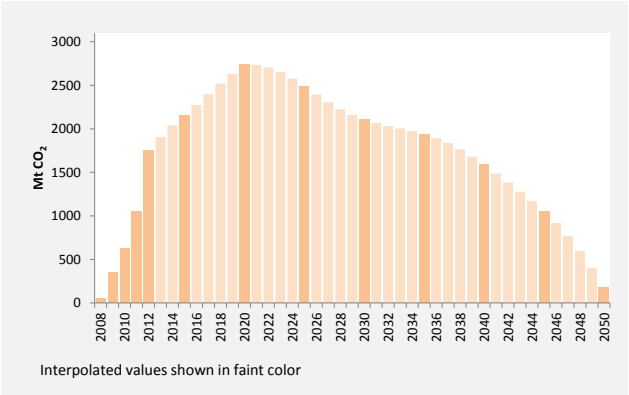


Phase II of the ETS has seen a rapid build-up of an allowances surplus which is banked into phase III, resulting from lower than expected emissions caused by the economic crisis unfolding as of 2008 and the early use of international credits. This surplus of allowances continues to increase in the short term, although there is economic recovery in the time period up to 2020. Together with the indicated drivers and complementary policies, risk-averse behaviour contributes to further banking of allowances until 2020

[15] Allowances include the permissible use of international credits.

(Figure 13)[16]. Beyond this time period, the gradually increasing ETS prices lead to a progressive use of previously banked allowances, which results in an almost complete exhaustion of the projected surplus by 2050. As emitters perceive the future carbon prices (perfect foresight), banked allowances are used particularly in the end of the projection period where the ETS price has increased substantially[17].

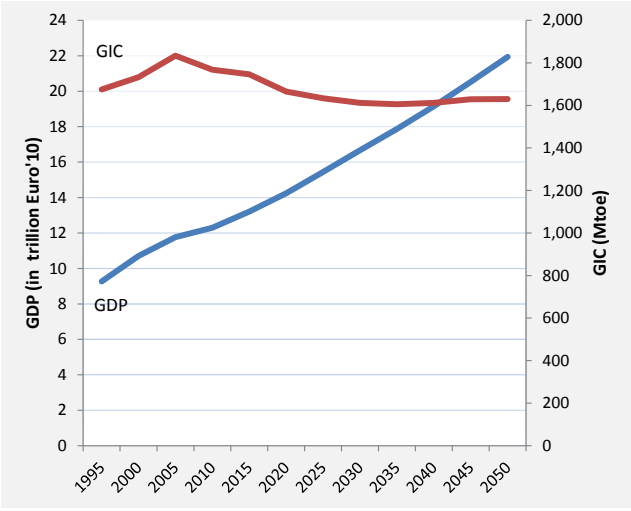
Energy consumption

The Reference 2013 scenario is characterized by accelerating energy efficiency improvements, in particular until 2020 and continuing throughout the remaining projection period – as demonstrated by the declining energy intensity of GDP. Gross inland consumption (GIC) and GDP growth decouple (Figure 14), a trend that is enhanced by the newly introduced legislation especially on energy efficiency and revised assumptions about economic growth. As becomes apparent in Figure 14, the shift from past increasing trends of energy consumption is occurring in the period 2005-10, where apart from relevant legislation, the economic crisis also has a downward effect on energy consumption. The downward trend on energy consumption commenced before the onset of the economic crisis, with EU energy consumption having peaked in 2006. Despite the gradual economic recovery after the crisis, GIC does not resume growth, instead it continuously decreases until 2035 and demonstrates a moderate increase thereafter, yet staying well below the 2010 level.

The projection indicates a shift in the fuel mix of GIC over time towards renewable energy forms (Figure 16). This also contributes towards lower energy intensity since many RES technologies (e.g. hydro, solar, wind) have, in statistical terms, an efficiency factor of 1 thus, the penetration of RES in all sectors, in particular in power generation, induces a further reduction in GIC, given that alternative fossil fuel or nuclear technologies would operate with lower efficiencies.

The main drivers of decreasing GIC are the developments in final energy demand. These reflect the implemented energy efficiency policies that include, among others, the Energy Efficiency Directive (EED), Energy Performance of Buildings Directive (EPBD), the Eco-design Directive and a host of implementing Regulations for specific products, CO_2 emissions standards for light duty vehicles etc. Following existing legislation until 2020, the assumed implementation of these measures is delivering significant energy efficiency improvements with effects going also beyond 2020. High international energy prices, as well as the relatively low growth rates projected for the energy-intensive industries, further reduce energy consumption. Beyond 2030, in the absence of additional policies on efficiency, final energy consumption follows an increasing pace, albeit slow. It is thus visible that the developments of the energy system in the decades 2010-20 and 2020-30 will have already set the ground for an economy with lower energy intensity. Finally, the ETS continues to indirectly support energy efficiency in the ETS sectors, throughout the projection period.

FIGURE 14: GIC IN RELATION TO GDP



[16] The absolute amount and time profile of the presented surplus is valid for the described and partly simplifying modelling assumptions taken, for example due to the cut-off date and given that the model proceeds in five year steps and the yearly data is based on interpolations and estimates. Other Commission analyses may therefore present different and more up to date results.

[17] ETS back-loading is not included in the modelling as no corresponding legislation exists at the time of this analysis.

FIGURE 15: ENERGY INTENSITY PROJECTIONS BY SECTOR[18]

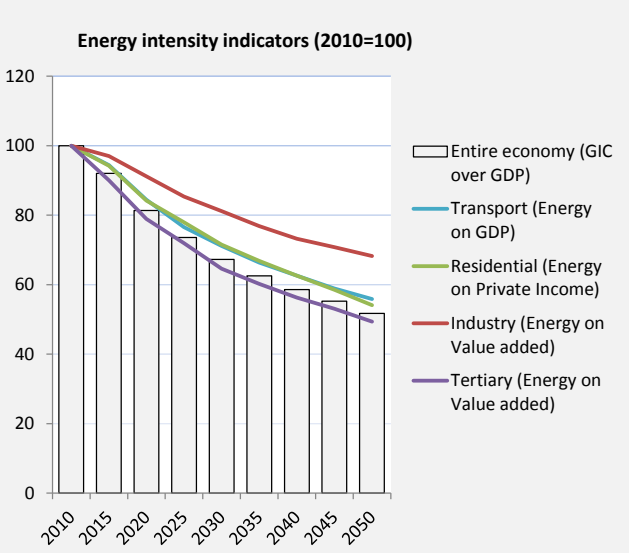


FIGURE 16: GROSS INLAND CONSUMPTION

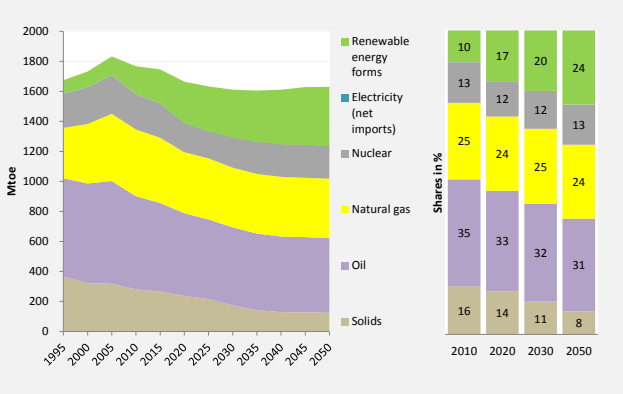

FIGURE 17: FINAL ENERGY CONSUMPTION

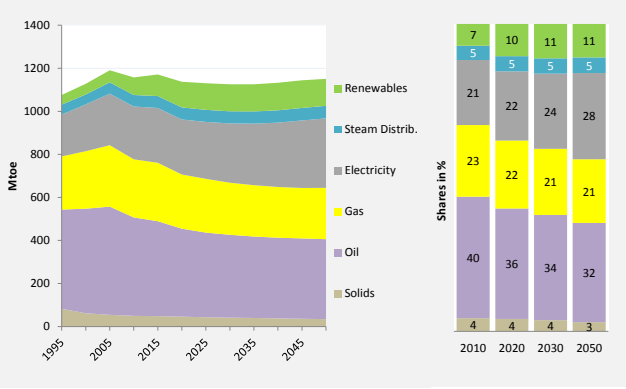

In addition to the considerable energy savings, the projection also indicates a switch in the fuel mix of final energy consumption over time, in favour of renewable energy forms (Figure 17). This shift is driven by the binding targets on RES and energy efficiency policies until 2020 with effects continuing until 2030, and by the ETS even beyond 2030. The share of oil decreases, but remains at a relatively high level as transportation is projected to remain dominated by oil. Consumption of solid fuels declines considerably throughout the projection period.

FIGURE 18: TRENDS IN ELECTRICITY DEMAND BY SECTOR

	Industry (incl.electricity for process CCS)	Households	Tertiary	Transport	Energy branch	Transmission distribution losses	Gross generation
'40-'50	0.5	1.1	0.6	1.2	1.6	0.9	0.8
'30-'40	0.0	1.5	0.8	2.0	1.0	1.2	0.9
'20-'30	-0.1	1.2	1.0	3.4	-0.8	1.1	0.7
'10-'20	0.7	0.1	0.1	2.8	-1.9	0.2	0.2
'00-'10	-0.2	1.7	2.9	-0.6	0.2	-1.0	1.0

In final energy demand, electrification is a persisting trend (Figure 18). This is due to two effects: a shift towards electricity for heating and cooling (due to higher demand for air conditioning and the introduction of electric heat pumps) and a continued increase of electric appliances in the residential and the tertiary sector (mainly IT, leisure and communication appliances). It is also the result of CO_2 standards for light duty vehicles and further electrification of rail – leading to higher uptake of electricity in the transport

[18] The ratio between the energy use and GDP is influenced not only by energy efficiency in transport but also by the evolution of the volume of transport activity to GDP. Therefore, in Figure 24 the relationship between transport energy consumption and transport activity is presented in addition to the relationship between transport energy consumption and GDP.

sector. In the period until 2020, when energy efficiency policies are being implemented, the growth rate of electricity demand is less than 0.5% per year up to 2020; thereafter, without specific energy efficiency policies the electricity demand growth rate becomes almost 1% per year.

In the following section, we present in detail the trends on final energy consumption by sector.

Industrial sector

The activity of the industrial sector is projected to recover from the current crisis and follow an increasing pace in the future, with the non-energy intensive sectors growing faster. This implies that energy consumption of the sector will grow at a slower rate relative to the activity of the sector. In parallel, following the trends of previous years, energy efficiency of production processes in the sector improves over time in order for the sector to remain globally competitive, with higher gains observed in the period until 2030 (Table 4) supported by the implementation of corresponding policies.

Overall, the trend on energy consumption is clearly upward for the period until 2015, following the recovery from the economic crisis; beyond 2015 and throughout the remaining projection period, energy efficiency improvements offset the effects from the growth of sectorial activity, and as a result energy consumption appears to change only moderately over time (Figure 19).

These trends are accompanied by a decline in the use of coal and oil, to the benefit of renewable energy forms (biomass and waste) and to a lesser extent electricity (Figure 20). This fuel shift is driven by the mandatory emission reductions that industrial activities should achieve in the context of the Integrated Pollution Prevention and Control (IPPC) and the Large Combustion Plant Directives (LCP), as well as because of national action for complying with the binding national targets of the Effort Sharing Decision (ESD) in the short-term (concerning the non-ETS industries) and the increasing ETS prices (concerning the ETS industries) mainly in the long-term. Switch to biomass and waste is also driven by the upward trajectory of fossil fuel prices and is compatible with the need for resource-efficiency, which will be one of the drivers of global competitiveness. Finally, the provisions on cogeneration in the EED in addition to the Cogeneration Directive promote the penetration of highly efficient cogeneration and the use of waste heat for steam generation in industrial sites.

TABLE 4: AVERAGE ANNUAL CHANGE OF ENERGY CONSUMPTION IN THE INDUSTRY SECTOR

Average annual change of energy consumption per unit of physical industrial output (%)				
per unit of physical industrial output (%)	*2010-00*	**2020-10**	**2030-20**	**2050-30**

FIGURE 19: FINAL ENERGY CONSUMPTION OF THE INDUSTRIAL SECTOR

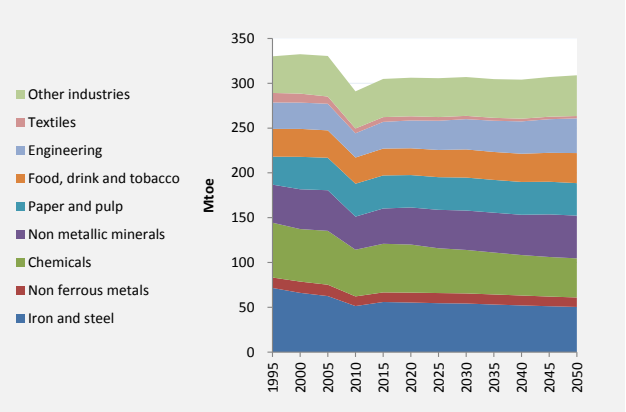

FIGURE 20: FINAL ENERGY CONSUMPTION OF THE INDUSTRIAL SECTOR BY ENERGY FORM

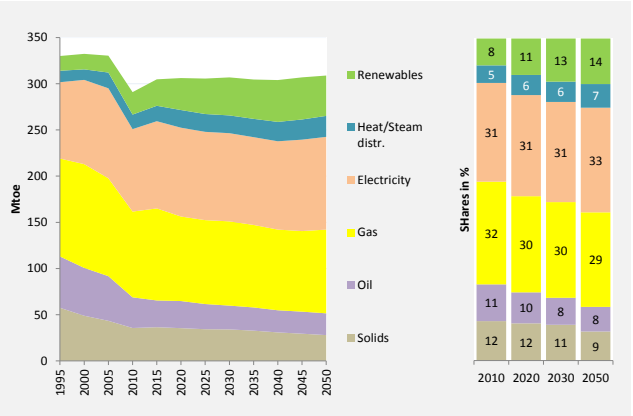


Residential sector

Energy demand in the residential sector is projected to stabilize in the short term. After 2015 and throughout the remaining projection period, final residential energy demand remains below the level of 2010. This is attributable to the fact that the portfolio of policies

and regulatory provisions (notably EPBD) for the residential sector that is assumed in the Reference 2013 scenario is very rich, and drives considerable energy efficiency savings.

In general, energy efficiency in the residential sector (as well as the tertiary sector) can be improved by:

- using more efficient energy equipment (e.g. lighting, electric appliances, heating and cooling appliances),

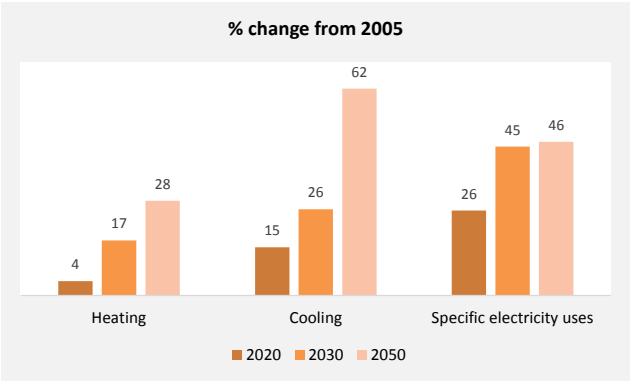
- upgrading energy characteristics of buildings (e.g. thermal integrity of buildings), or

- inducing changes in energy consuming behaviour.

In the Reference 2013 scenario, there is a general improvement in the efficiency of energy using equipment across the EU which is related to the effects of the implementation of relevant policies. These policies include notably the EED including the savings obligation on distribution companies and retail sellers, the provision on the exemplary role of public authorities as well as all the other provisions stimulating more energy efficient behaviour. In addition, eco-design standards as well as energy performance of buildings requirements as well as "soft" measures, such as public campaigns play a role along with measures improving transparency for allowing more energy efficient choices (Labelling Directives).

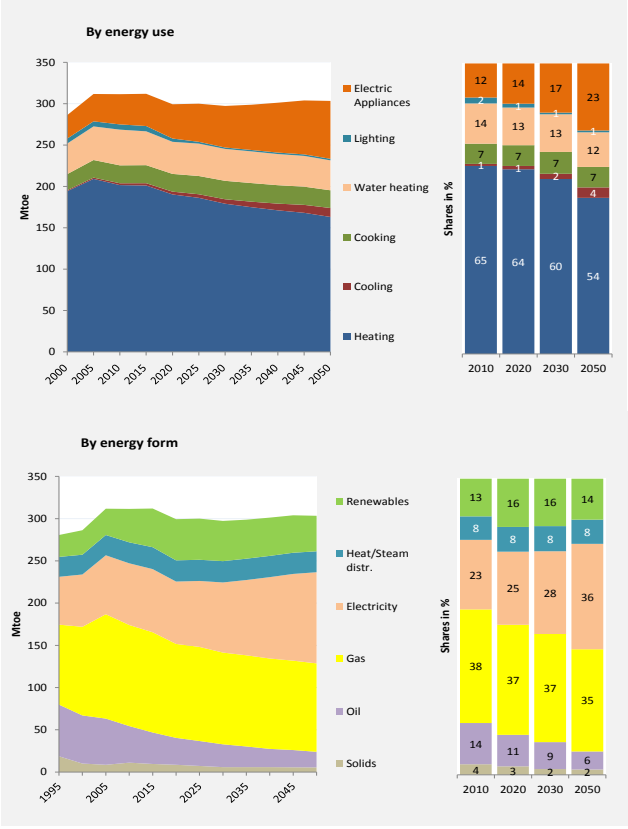
Regarding the energy efficiency obligations on buildings and strict building codes (included both in the EPBD and the EED), they drive investment choices improving thermal integrity of houses and efficiency of heating appliances, with overall final energy demand for heating and cooling purposes decreasing by 8% in 2020, 12% in 2030 and 17% in 2050 relative to 2005. Energy consumed for heating purposes drops to 2000 levels already by 2020 and further decreases thereafter (Figure 22). Regarding the use of different energy forms, increased efficiency requirements drive a shift towards the use of electric heat pumps, which is partly the reason of the increasing shares of electricity consumption in the residential sector. Additionally, the use of heating oil decreases to the benefit of gas, especially beyond 2030, in part because of the relatively low natural gas prices (in comparison to oil).

FIGURE 21: IMPROVEMENTS IN EFFICIENCY OF THE ENERGY EQUIPMENT IN THE RESIDENTIAL SECTOR COMPARED TO 2005



The main reason behind the continuous electrification of the sector, as demonstrated in Figure 22, is the increasing penetration of electric appliances and their quality improvements. This concerns mainly “black” appliances (mobile phones, TVs, PCs etc.). At the same time eco-design regulations drive significant energy savings in specific electricity uses; the average efficiency of appliances and lighting improves by approximately 25% in 2020 and by 45% in 2030, relative to 2005.

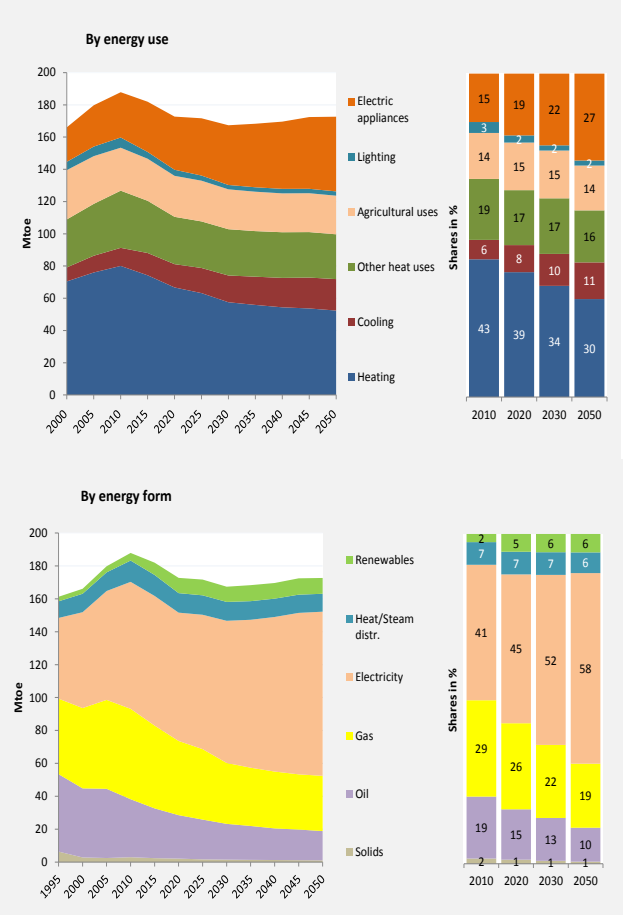
FIGURE 22: FINAL ENERGY DEMAND IN THE RESIDENTIAL SECTOR



Tertiary sector (services and agriculture)

Projections of final energy demand in the tertiary sector follow the same trends as for the residential sector; energy consumption decline strongly between 2010 and 2020, followed by a decade of moderate decrease and a slight increase after 2030. Energy efficiency gains brought about by eco-design policies, energy efficiency policies stemming notably from obligations under the EED and policies on the energy performance of buildings, are very significant, and over-compensate the effects of increasing sectorial activity up to 2030, driving final energy demand below 2010 peak levels throughout the entire projection period. Marked efficiency progress is observed both for heating and for specific electricity consumption, in particular in the medium term (2020-30), driving energy consumption downwards in the period 2010-30, contrasting past increasing trends (Figure 23). Beyond 2030, where no additional energy saving policies are implemented, energy consumption resumes an increasing, albeit slow, pace of growth.

FIGURE 23: FINAL ENERGY DEMAND IN THE TERTIARY SECTOR



Electrification of the tertiary sector is very significant. The considerable increase in electricity consumption concerns primarily the use of electric appliances and the use of electricity for heating and cooling purposes (heat pumps). The use of heating oil and gas follows a decreasing trend, which is steeper in the period up to 2030, attributable to energy efficiency policies. Throughout the projection period, gas substitutes oil for heating purposes.

Transport sector

The activity of the transport sector is growing significantly with the highest growth rates occurring from 2010 to 2030, driven by developments in economic activity. This concerns both passenger and freight transport. Freight transport in particular is growing at higher rates than passenger transport, following more closely the GDP developments.

Beyond 2030, the activity of passenger transport continues to grow albeit at slow rates, as a result of stagnant and after 2040 decreasing population, deceleration in GDP growth and saturation of passenger car demand.

Freight transport follows a similar trend to passenger activity after 2030, resulting from the slow-down of GDP growth as well as from the shift of economic activities towards services and limits to distant sourcing and off-shoring.

Road transport is expected to maintain its dominant role in passenger transport by 2050, despite growing at lower pace relative to other modes (0.6% p.a.). Passenger cars alone would represent about 67% of total passenger transport activity in 2050 although their modal share would decrease by about 7 percentage points between 2010 and 2050. As previously mentioned, the growth slowdown for passenger cars activity could be explained by the car ownership which is close to saturation levels in many EU15 Member States but also by the high congestion levels, the increase in fossil fuel prices and the ageing of the EU population. Transport activity of buses and coaches and powered 2-wheelers would grow at slightly higher rates than passenger cars activity by 2050, 0.7% p.a. and 1.1% p.a., respectively. Overall, the share of road transport (including buses and coaches and powered 2-wheelers in addition to passenger cars) in total passenger transport activity

would go down from about 84% in 2010 to 76% in 2050.

Air transport is projected to be the highest growing of all passenger transport modes, going up by 133% between 2010 and 2050 (2.1% p.a.), mainly due to the large increase of international trips (e.g. to emerging economies in Asia). Higher potential for air traffic growth (3.1% p.a. for 2010-2050), including for international holiday trips, is expected in EU12 MS due to their less mature markets and faster growing GDP per capita. Aviation activity in EU15 would increase at a lower rate compared to EU12 due to weaker growth of GDP per capita and the available capacity at the airports. Overall, air transport is expected to increase its modal share by about 5 percentage points, from 8% in 2010 to 13% in 2050, and become the second most important passenger mode after road transport.

Passenger rail activity is projected to increase by 79% during 2010-2050 (1.5% p.a.) and expand its modal share by 2 percentage points (from 8% in 2010 to 10% in 2050), driven in particular by the completion of the TEN-T core network by 2030 and of the comprehensive network by 2050. High-speed rail sees a significant increase in terms of volume (2.5% p.a. during 2010-2050) and share as a result of the infrastructure build-up and the upgrade of existing railway lines. About 37% of passenger rail traffic, expressed in passenger-kilometres, would be carried by high-speed rail by 2050.

Passenger rail competes with both road and air transport. In EU15 a relatively important share of additional demand would be covered by rail (in most cases high-speed rail where investments are foreseen), considering the saturation of passenger car demand. The increase of fossil fuel prices also shifts part of the passenger road traffic to rail. In addition, high-speed rail attracts demand from short-haul air travel.

Inland navigation[19] holds a small share of total passenger transport activity and projections show a moderate increase at EU level (0.7% p.a. between 2010 and 2050).

Freight transport activity showed steady growth between 2005 and 2007, continuing the 1995-2005 trend. However, the economic crisis led to a reduction of activity in the subsequent years resulting in lower levels in 2010 compared to 2005. The projections show an increase in the total freight transport activity by about 57% (1.1% p.a.) between 2010 and 2050. Notably, the strong growth in activity (1.7% p.a.) in the short-term (up to 2015), driven by GDP developments, allows the recovery of freight transport activity to pre-crisis levels.

Freight traffic shows strong correlation with GDP growth until 2030. The completion of the TEN-T core network by 2030 and of the comprehensive network by 2050 is expected to provide more adequate transport infrastructure coverage and support a concentration of trans-national traffic and long-distance flows. It is also expected to provide support for logistic functions and improve inter-modal integration (road, rail, and inland navigation), through the innovative information management systems which are part of the network, and reduce the time losses caused by road congestion. As already mentioned, beyond 2030, weaker growth prospects together with shifts in GDP composition towards services and information activities and limits to distant sourcing and off-shoring contribute to a certain weakening in freight transport activity.

Road freight traffic is projected to increase by about 55% between 2010 and 2050 (1.1% p.a.), but growth is unevenly distributed between the EU15 and EU12. The highest growth in road freight transport activity would take place in the EU12 (72% for 2010-2050, equivalent to 1.4% p.a.) where a strong correlation with GDP growth can be observed. Overall, road freight sees a slight reduction in its modal share, from 71% in 2010 to 70% in 2050.

By 2050, rail freight features the highest growth among the freight transport modes (79%, equivalent to 1.5% p.a.) and increases its modal share from almost 16% in 2010 to 18% in 2050. The significant increase in rail freight transport activity is mainly driv-

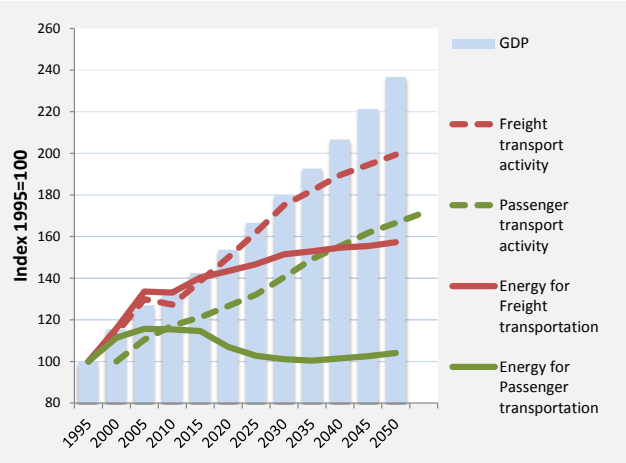
[19] Inland navigation includes inland waterways and national maritime transport.

en by the completion of the TEN-T core and comprehensive network; thus improving the competitiveness of the mode.

Inland navigation traffic also benefits from the recovery in GDP growth and the completion of the TEN-T core and comprehensive network, including support for the logistic functions and improved inter-modal integration, and is thus projected to grow by 41% between 2010 and 2050 (0.9% p.a.). However, the relatively stronger growth in road and rail traffic leads to a slight decrease in its modal share, from about 13% in 2010 to 12% in 2050.

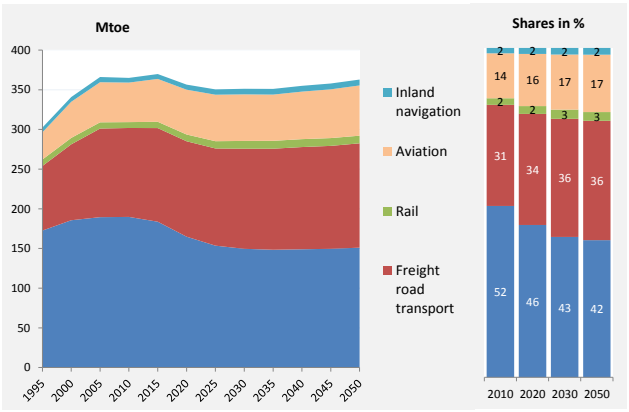
Historically, final energy demand in the transport sector has grown in line with the transport activity. However, despite the projected upward trends in transport activity beyond 2010, final energy demand stabilizes by 2050 to levels marginally lower than those observed in 2010. The projections show some weak growth in energy demand (0.3% p.a.) in the short-term (up to 2015), mainly driven by the strong recovery in the freight transport activity following the crisis. Beyond 2015 however, energy demand is decoupling from transport activity (Figure 24).

FIGURE 24: TRENDS IN TRANSPORT ACTIVITY AND ENERGY CONSUMPTION



The main driver of low final energy demand from transport relative to transport activity is the improvement in fuel efficiency driven by policies, in particular for passenger cars and light commercial vehicles (Figure 26) and the uptake of more efficient technologies for other transport means. In order to comply with the regulations on CO_2 emissions standards for Light Duty Vehicles (LDVs), covering passenger cars and light commercial vehicles (LCVs), manufacturers have to introduce more fuel efficient LDVs into the market. In particular, in passenger road transport energy efficiency of vehicles improves by 21% in 2020 and 35% in 2030 relative to 2005 (Figure 26), leading to a decline in energy demand in passenger road transport by 2030. Beyond 2030, energy demand of passenger road transport stabilizes. Efficiency gains, driven by increasing fuel prices and techno-economic developments, evolve at slower pace in lack of more stringent CO_2 emissions regulations.

FIGURE 25: FINAL ENERGY DEMAND IN TRANSPORT

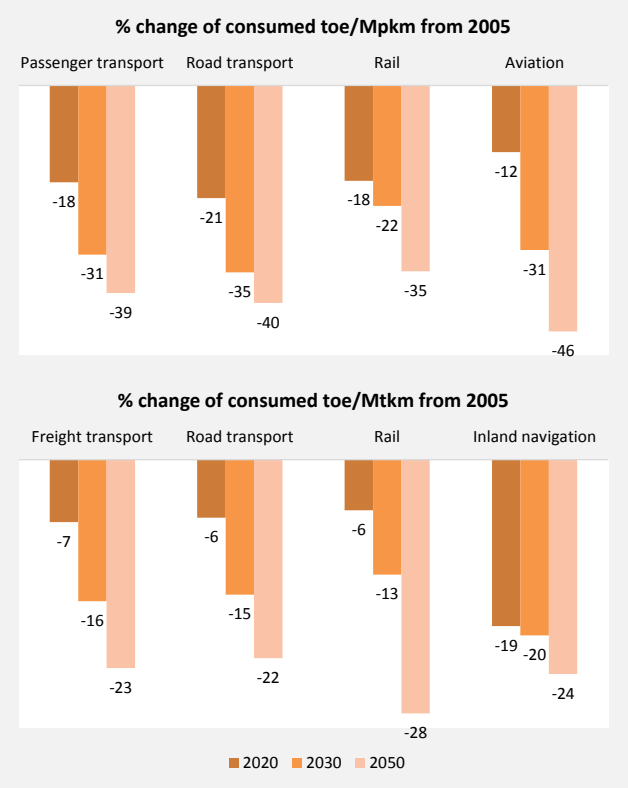


Other passenger transport modes also contribute to the decoupling between activity and final energy demand. However this contribution is more apparent in the longer term, from 2030 onwards. Aviation activity increases considerably throughout the projection period leading to increased energy demand. Nonetheless, energy demand grows less than activity as aviation experiences high efficiency gains owing to the introduction of more energy efficient aircrafts and the renewal of the fleet[20]. Efficiency improvements in aviation amount to 12% in 2020 relative to 2005, and 31% by 2030. Passenger rail features some relatively lower rates of improvement in efficiency by 2030 compared to road and aviation. In addition to the currently high efficiency of rail relative to other transport means, the long lifetime of the rolling stock delays its renewal and therefore the improvements in efficiency.

[20] The International Air Transport Association (IATA) has set ambitious targets to curb fuel consumption and mitigate GHG emissions from aviation in its Carbon Neutral Growth initiative, according to which the aviation industry has committed to an average improvement in fuel efficiency of 1.5% per year by 2020 and a cap on aviation CO_2 emissions from 2020 (carbon-neutral growth). By 2050 the CO_2 emissions from aviation should be reduced by 50% relative to 2005 levels. Source: http://www.iata.org/pressroom/facts_figures/fact_sheets/pages/environment.aspx.

The improvements would be mainly attributed to fuel substitution; in particular switching from diesel to electricity in areas where electrification is an economically viable option and in line with the provisions of specific initiatives by MS.

FIGURE 26: TRANSPORT EFFICIENCY IMPROVEMENT



Efficiency improvements also take place in freight transportation, and moderate the effect of the increasing activity (which is growing stronger than for passenger transport) on energy demand. Heavy goods vehicles (HGVs), which throughout the projection period account for more than 80% of energy consumed in freight transport, undergo improvements in specific fuel consumption driven in particular by the increasing fossil fuel prices. Fuel costs represent a considerable part of operational costs of HGVs and their minimization is among the main objectives of HGV manufacturers and fleet operators. Improvements in technology, related among others to vehicle design or vehicle powertrain, aim to reduce vehicle specific fuel consumption. The reductions in vehicle specific energy consumption of HGVs become more apparent in the long term, as the renewal rate of the HGV fleet is slow. LCVs on the other hand, show high efficiency gains already by 2020 as a result of CO_2 emissions regulations, but their effect on energy demand of freight road transportation is not significant due to their small share in energy demand. Overall, fuel consumption in road freight transport per Mtkm is projected to decrease by 6% in 2020, 15% in 2030 and 22% in 2050 relative to 2005.

Freight rail follows similar developments as passenger rail; it sees moderate improvements in specific energy consumption, partly driven by the substitution of diesel by electricity. However, by 2050 the efficiency gains in rail freight are somewhat higher than for road freight, in lack of specific policies for CO_2 emissions reduction or energy efficiency of newly registered HGVs. By 2050, improvements in specific fuel consumption for inland navigation amount to 24% relative to 2005, slightly lower than those achieved in rail freight.

The obligation to meet CO_2 standards for LDVs is reflected in the change of the transport fuel mix (Figure 27). Emissions performance standards for vehicles together with favourable taxation of diesel by some Member States result in wide scale substitution of petrol with diesel in conventional passenger cars, and favor the introduction of diesel hybrid vehicles (Figure 28)[21]. Consumption of petrol declines considerably until 2030 and stabilizes from thereon to 2050, as no more stringent requirements for fuel-efficiency are introduced. Consumption of diesel increases by 2015 and stabilizes in the period 2015 to 2050, becoming the dominant fuel in passenger cars and continuing to be the primary fuel for heavy duty vehicles (HGVs, buses and coaches). Heavy duty vehicles have little potential to switch to alternative fuels such as LNG as this would require significant investments in infrastructure build-up across the EU, which is not assumed to be the case in the Reference 2013 scenario[22].

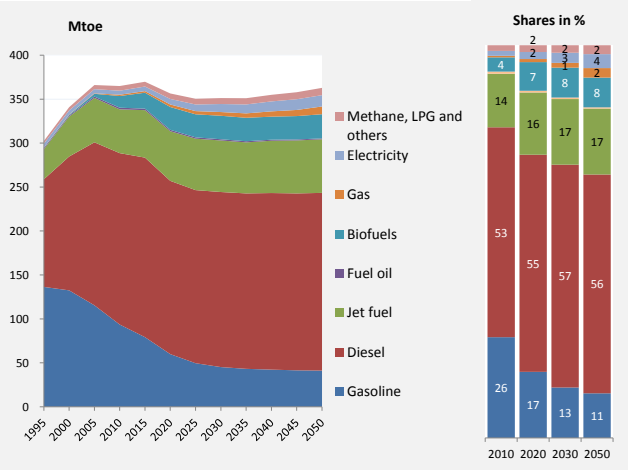
Consumption of jet fuels in aviation increases steadily by 2050 due to the increase in transport activity and despite improvements in efficiency; fossil fuels continue to dominate, and only after 2035 biofuels (biokerosene) slowly start penetrating the aviation fuel mix - driven by high ETS prices.

[21] Despite the relatively higher carbon intensity of diesel, diesel-fueled vehicles are more fuel economic than gasoline-fueled vehicles.

[22] The Clean Power for Transport package, adopted by the European Commission in January 2013, is not reflected in the Reference scenario 2013.

Biofuels in general, make significant inroads in transport by 2020, driven by the legally binding target of 10% renewable energy in the transport sector (RES-T target). In parallel with the shift towards diesel vehicles, the share of biodiesel consumption increases, also driven by its uptake in road freight transport. Beyond 2020, with no further tightening of the RES-T target, biofuels maintain their share as a result of improved economics of the biofuel supply side and the increasing fossil fuel prices.

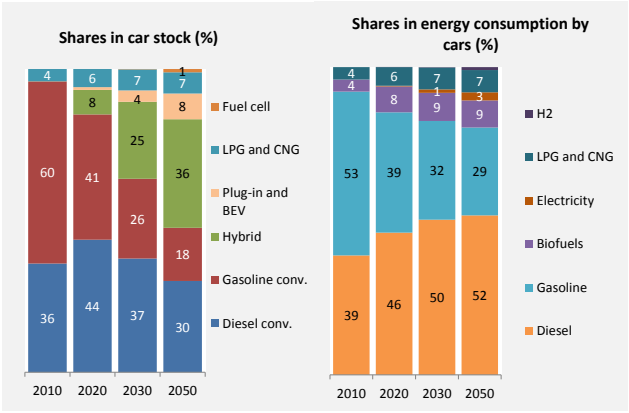
FIGURE 27: FINAL ENERGY DEMAND IN TRANSPORT BY FUEL TYPE



Electricity consumption in transport sees a steady increase as a result of rail electrification and the penetration of alternative electric powertrains in road transport. Electrically chargeable vehicles (EVs), in particular in the segment of passenger cars and LCVs, emerge around 2020 as a result of EU and national policies as well as incentive schemes aiming to boost their penetration. Plug-in hybrids (PHEVs) hold the largest share among EVs due to their ability to use both power-trains alternatively (internal combustion engine or electric motor) and they would represent two thirds of EVs in 2050. Some improvements in battery costs are assumed to occur allowing for a decrease in capital costs together with slow increase in infrastructure availability. The penetration of electric vehicles occurs mainly in niche markets, in urban areas for urban commuting and municipal fleets, due to limited range of vehicles, which is assumed to persist. By 2050 the share of electric vehicles in the total stock of cars reaches approximately 8% (Figure 28).

Finally, other energy forms such as LPG and natural gas maintain a rather small share in the final energy demand of the transport sector. Passenger cars running on LPG and CNG see a moderate increase especially stemming from countries with re-fuelling infrastructure already in place; in Member States where such infrastructure is currently not in place the uptake of CNG and LPG vehicles on a commercial basis is limited in the Reference 2013 scenario.

FIGURE 28: STRUCTURE OF PASSENGER CARS FLEET AND FUEL CONSUMPTION



Power generation

Developments in power generation in the Reference 2013 scenario are driven by the implementation of RES policies to the horizon of 2020 and by growing ETS carbon prices – also in the longer term, especially after 2030. Both induce high level of RES penetration in power generation throughout the projection period, in particular variable RES, which are demanding in terms of balancing services and system reserves. In order to support the penetration of RES, the requirements for capacity back-up by thermal plants are high, and are met in the projection by investments on flexible gas plants and by extensions of lifetime of old (typically open cycle) plants.

In the short term, in particular up to 2020, developments are characterized by two main aspects: 1) the necessity to achieve the RES targets, and 2) planned investments in existing and new power plants. The first necessity stimulates RES growth whereas the second determines to a large extent the developments in conventional power plants. Considering the very long lead times for large (in particular) conventional plants, investments that will take place up to 2020 are already known today. The PRIMES model

fully includes in its database all currently known planned investments, including lifetime extensions as well as planned decommissioning, based on commercial databases (e.g. Platts) and plans of large companies in all the Member States. The projections of large investments in this decade are strongly determined by such known investments and decommissioning plans.

The Reference 2013 scenario also considers country specific potentials for RES penetration in addition to the specificities by Member States in policies regarding nuclear and CCS options. Moreover, the scenario assumes completion of the internal energy market and the successful implementation of the 10-year network development plan of ENTSO-E (TYNDP), which entails considerable investments in electricity transmission systems. These infrastructure developments include refurbishment or construction of transmission and distribution power lines, the extension of the grid, enabling capacity additions and supporting the integration of the high levels of intermittent RES in the system. Moreover, they allow for a general increase of net transfer capacities (NTC) values, thus leading to a higher potential for trade within the internal energy market. The possibility to make more extensive use of interconnectors and new transmission grids allows for use of sites with lower costs, even when these are far away from consumption centres. As a result the fully interlinked system allows for better optimisation of resources and capacity expansion.

Regarding carbon capture and storage (CCS) the PRIMES model has been updated to take into account the difficulties that this technology has been encountering over the past years related to the development of demonstration plants and storage facilities. The cost of CCS power plants construction has been revised accordingly making the technology more expensive, in particular the storage cost-supply curves as well as the technology itself. In countries (e.g. Austria) with stringent legislation, the storage costs are extremely high, making investments in CCS storage uneconomical throughout the projection period.

Also the assumptions on nuclear have radically changed compared to previous projections based on recent policy developments, changed economic situation and detailed surveys into the possibilities of extending the lifetime of existing power plants. The possibilities of extension of lifetime for power plants have been analytically assessed through a plant by plant survey based on the age, construction type (generation) of the power plant and national legislation. The construction of new power plants on new sites (i.e. in locations where there are currently no power plants) has become considerably more expensive based also on issues related to public acceptance. The construction of new power plants on existing nuclear sites is limited based on surveys which assess the possibilities (e.g. based on spatial limitations) of expansion in existing locations. The model updates concerning limitations, the new national legislation and the higher costs lead to lower perspectives for nuclear than in past projections.

Electricity generation

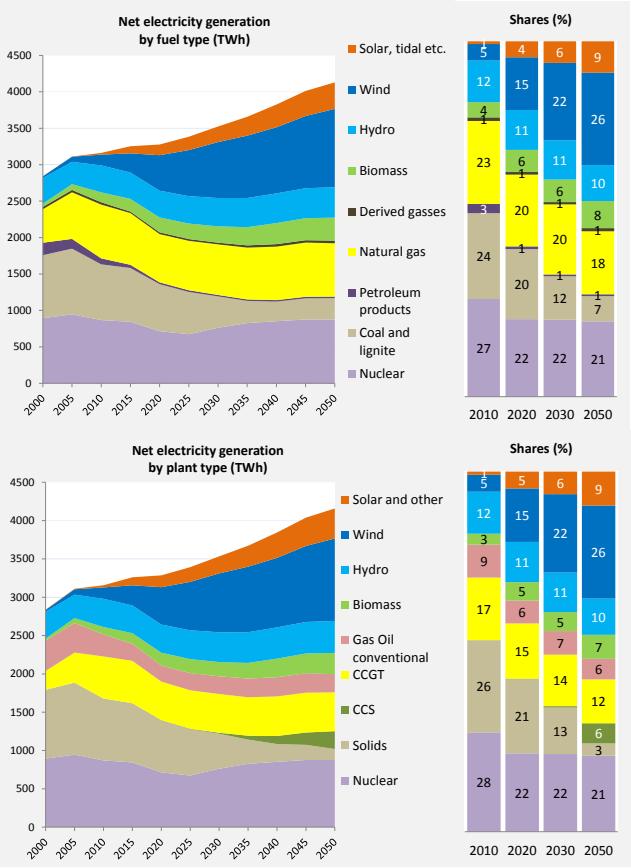
In the short term, the set of EU and national specific policies that promote RES (notably implementation of supportive financial instruments such as feed-in-tariffs) drive significant penetration of RES in power generation. The binding short-term RES targets are assumed to be achieved in the Reference 2013 scenario. RES expansion is also facilitated by the assumed developments of grids and new equipment for controlling grid operation, especially in the case of smart grids. Up to 2020, the share of RES in electricity generation (RES-E indicator[23]) reaches 35%, a significant increase from the 20% in 2010. Beyond 2020, no binding targets on RES are currently set, however the share of RES in electricity generation continues to increase attaining 43% in 2030 and 50% in 2050, driven by the increasing ETS prices, along with the continuation of some direct support schemes[24] and a continuation of enabling policies, such as streamlined authorization procedures, priority

[23] Calculated according to the definitions of the RES Directive used also for the pertinent provisions of EUROSTAT statistics

[24] After 2020, feed-in tariffs or equivalent support schemes are substantially reduced depending on the maturity of the technology and the MS.

access, where applicable, and the benefits that local population may have from investing in local RES.

FIGURE 29: ELECTRICITY GENERATION BY FUEL AND BY PLANT TYPE



While RES provide growing shares in electricity generation (up to 50% in 2050), the contribution of variable RES (solar, wind as well as tidal/wave in the definition used here) remains significantly lower. These variable RES combined account for 19% of total net electricity generation in 2020, up from only 5% in 2010. Their share is rising to 28% in 2030 and 35% in 2050.

Wind provides the largest contribution from RES supplying 15% of total net electricity generation in 2020, rising to 22% in 2030 and 26% by 2050. A share of 30% of total wind generation is produced from wind off-shore capacities from 2020 onwards. Total wind capacities increase to 205 GW in 2020, 305 GW in 2030 and 413 GW in 2050, up from 85 GW in 2010, of which around a quarter is installed off-shore in 2020 and beyond; higher full load hours of off-shore wind allow for the higher share in generation compared with capacity for off-shore wind.

Generation from PV contributes 4% in net generation by 2020. Beyond 2020, PV generation continues to increase up to 6% in 2030 and 9% in 2050; PV capacity is projected to reach 110 GW in 2020, up from 30 GW in 2010. Investment is mostly driven by support schemes and the decreasing costs of solar panels. While support schemes are being reduced, costs continue to fall and total PV capacities reach 149GW in 2030 and 231GW in 2050.

The use of biomass and waste combustion for power generation also increases over time, both in pure biomass plants (usually of relatively small size) and in co-firing applications in solid fuel plants; biomass attains a share in fuel input in thermal power plants of 16% in 2020, 19% in 2030 and 26% in 2050[25]. Biomass also becomes very significant in CHP, in which it contributes 33% in 2020, reaching 35% in 2030 and 41% in 2050. Biomass plant capacities reach 35 GW in 2020, up from 25 GW in 2010, 39GW in 2030 and 66 GW in 2050. Above 50% of biomass power plants use solid biomass; biogas use increases in the short term and reaches a share of approximately 25% by 2020, with a slight increase in the remainder of the projection period.

The relative contribution of hydro generation remains rather constant at 10-11% of total net generation, with small hydro slightly increasing. The share of geothermal electricity generation rises from 0.2% in 2020 to reach 0.6% in 2050. Tidal and wave, which mainly develop after 2020 in a few MS with such resources, represent 0.2% of total EU net generation by 2030, reaching 0.4% at the end of the projection period.

Generation from conventional thermal plants decreases continuously up to 2030 and stabilises thereon, supported by the introduction of CCS. The introduction of CCS starts with the demonstration plants

[25] Calculated following EUROSTAT definitions, i.e. excluding energy consumed by Industrial sectors and refineries for on site CHP steam generation.

built up to 2020,[26] but only minor additions occur in the projection until 2030. CCS develops mainly after 2030 reaching 1.7% of gross electricity generation in 2035 and rising further to 7% by 2050. In 2050, total net CCS generation capacity amounts to 38 GW. CCS power generation in this scenario requires a cumulative storage capacity of approximately 670Mt CO_2 up to 2050. The distribution of CCS by country is very uneven as the analysis is considering the specific policies as well as the availability of storage sites by MS[27].

Generation from solid fuels declines significantly throughout the projection period, in particular in the period 2030-50, as ETS prices increase considerably. Investment in non-CCS solid fuel plants after 2020 amount to 33.6 GW, whereas 32.4 GW are added in the decade 2011-20. Phasing out of solid generation is very intense, as availability of CCS technologies is relatively limited. By 2050, more than half of solid-fuelled generation is produced from facilities with installed CCS technologies.

Gas-fired generation slightly decreases until 2020, but increases thereafter, in 2050 reaching the same levels as in 2010. Total investment in gas-fired plants in the period 2011-50 amounts to net 335 GW (225 GW gas plants are operating in 2010). This strong increase in gas capacity despite rather stagnant generation from gas highlights the key role that gas is increasingly playing as a back-up technology for variable RES.

The interplay of continuously declining ETS allowance supply, RES policies and the demand levels stemming from the level and structure of energy consumption entails only limited gas investment given the existing plants and new investments (notably for coping with RES targets) and the effects of energy policies, especially on energy efficiency. The power plant investments have been modelled in each period taking account of all relevant factors, in particular of the ETS price, while the ETS price in turn is influenced by such investments. The increase in ETS prices therefore counteracts the increasing effect on emissions that would otherwise occur from the relatively low natural gas price.

Gas plays a crucial role in the context of emission reduction targets and increased penetration of intermittent RES. As a fuel it is less CO_2 emissions intensive relative to other fossil fuels, and gas units are flexible enough to serve the increased balancing requirements of RES. Overall, generation from gas power capacities provides around 20% of total net generation up to 2040, falling only 1 percentage point in the decade to 2050. The contribution of gas to total net thermal generation ranges between 45% and 55% throughout the projection period. Generation from CCGT in particular constitutes 35% and 42% of total thermal generation in 2020 and 2030 respectively, reaching 45% in 2050. Industrial gas technologies serve CHP purposes, while gas peak devices reach 7% of total thermal generation at the end of the projection period.

Cogeneration develops significantly in the Reference 2013 scenario, driven by the corresponding provisions of the EED. The share of gross electricity produced by CHP plants attains a level around 16% throughout the period from 2020 until 2050, significantly up from 13% in 2010.

Specific nuclear phase-out policies that have been adopted by some EU MS (Germany and Belgium), along with the higher cost induced by increased security requirements, drive electricity generation from nuclear downwards in the short term (up to 2025). Thereon, the projected level of investments surpasses decommissioning of nuclear capacity and by the end of the projection period installed nuclear capacities are almost equal to 2010 levels. Participation of nuclear in the generation mix remains, however, lower than today, reflecting rising electricity generation volume. The projected investments in nuclear capacity mainly occur on existing sites or are lifetime extensions through retrofitting; there are very few projected investments in nuclear capacities on new sites. Out of

[26] The included power plants are: UK (White Rose) 0.4478GW net capacity, coal CCS; Netherlands (Rotterdam Capture and Storage Demonstration Project-ROAD) 0.227GW net capacity, coal CCS; Poland (Belchatow) 0.2294 GW net capacity, coal CCS.

[27] In PRIMES it is assumed that no cross-border trade of CO_2 is possible therefore the CO_2 captured in a country must also be stored in the same country.

the 176GW of capacity additions, only 12GW are capacities constructed on new sites.

Considering the cumulative investments in the period 2011-50, retrofitting investments constitute approximately one third of overall investments. As the share of non-dispatchable generation (variable RES) in the system is increasing, profit margins of conventional generation are diminishing[28] thus undertaking large new investments in dispatchable capacities risks becoming increasingly uneconomic. Retrofitting investments, where possible, are desirable from an economic perspective, despite their short lifetime, due to their low capital intensity compared to the construction of new plants.

Following the retirement of obsolete thermal capacity and strong investment in modern thermal power plants there is an on-going trend towards higher efficiency of thermal electricity generation. This happens despite an increasing share of CHP, which optimises the combined generation of electricity and heat from the same input fuel. Overall, CHP contributes to greater energy efficiency. This feature is not present for CCS, which actually requires more energy for the same output, but delivers this electricity output almost carbon free. As can be seen from Table 5 the shares of zero (RES, nuclear), and low carbon technologies (here: CCS) are rising or at least remaining stable after 2020 (nuclear).

Finally, in the context of high intermittent RES power generation, the projection shows increasing volumes of electricity trade over time to cover balancing requirements (Table 6). This is possible under the assumption of higher potential of trade in the internal energy market, induced by the successful development of the TYNDP.

FIGURE 30: INSTALLED POWER CAPACITIES

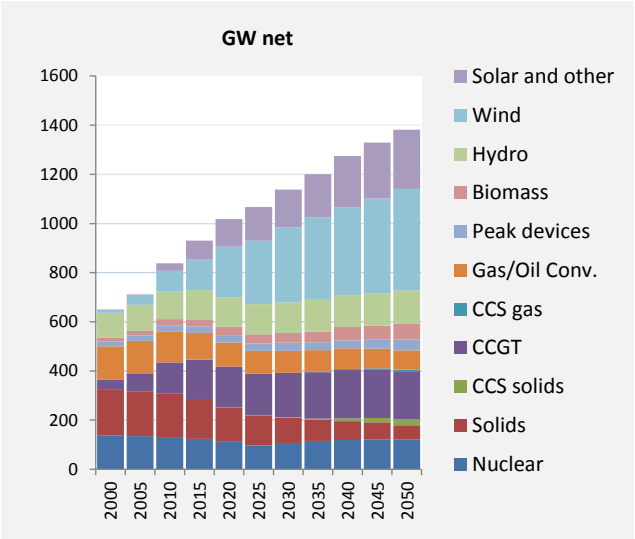


FIGURE 31: PROJECTED CAPACITY ADDITIONS

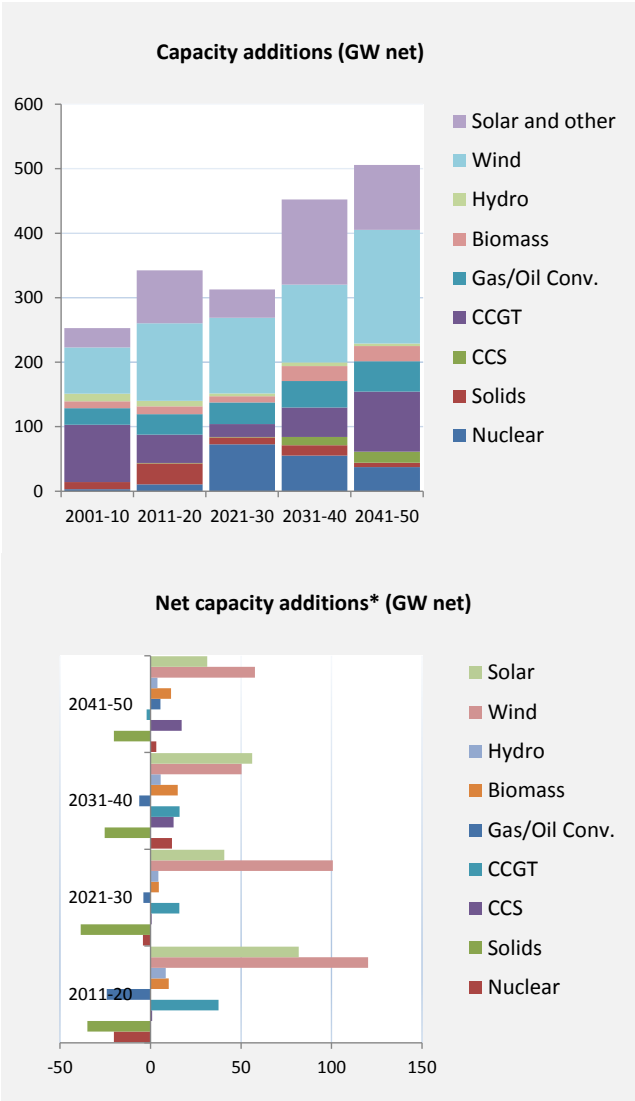

** capacity additions minus decommissioned capacity*

[28] Reflecting, among other things, lower wholesale prices following substantial supply from capacity with close to zero marginal costs over large parts of a typical day including around a noon peak of demand.

TABLE 5: INDICATORS OF POWER GENERATION

	2010	2020	2030	2050
Efficiency for thermal electricity production (%)	38.4	40.8	42.7	44.6
CHP indicator (% of electricity from CHP)	12.6	15.8	16.1	16.2
CCS indicator (% of gross electricity from CCS)	0.0	0.2	0.5	6.9
Non-fossil fuels in electricity generation (%)	48.5	58.0	66.3	72.8
- nuclear	27.5	21.9	21.8	21.3
- renewable energy forms and industrial waste	21.0	36.1	44.5	51.6

TABLE 6: VOLUME OF ELECTRICITY TRADE[29]

Sum of all export and import flows of electricity as simulated by the model				
	2010	2020	2030	2050
Nordic	21.6	45.4	57.8	93.6
British islands	5.2	22.9	16.1	14.6
North-West EU	54.8	94.4	137.2	110.9

with outside Europe	23.4	10.7	15.5	9.9
Total	248.1	317.6	404.8	485.3

Steam and heat supply

Steam and heat demand continues to grow in the EU28 till 2020 and then stabilises. Main sources of demand are industry and households.

On the supply side, as explained above, the role of cogeneration develops significantly in the Reference 2013 scenario, driven by the corresponding provisions of the EED.

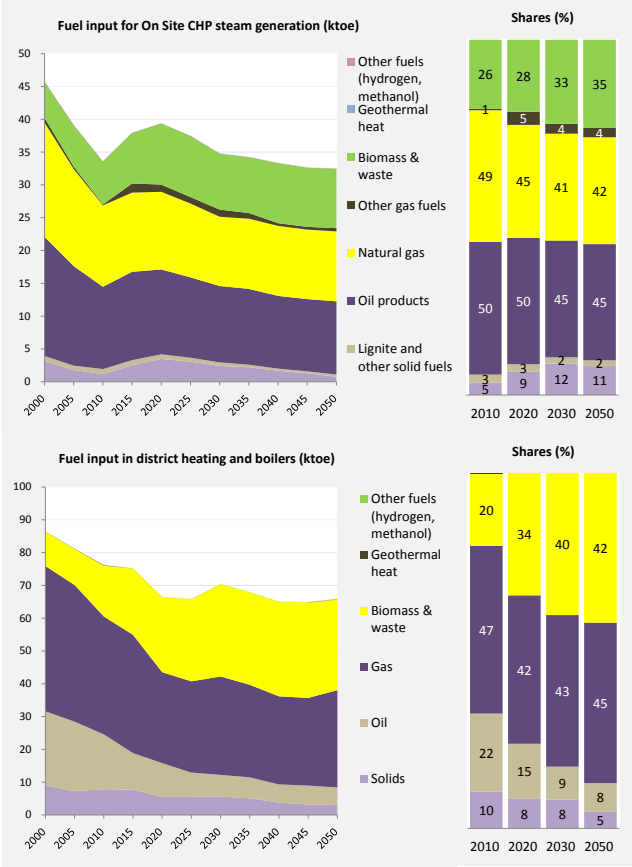
While electricity generation from CHP plants increases throughout the projection period, steam output increases up to 2020 and remains almost constant throughout the projection period.

The role of cogeneration in steam and heat supply grows from 73% in 2010 to 76% in 2030 and 80% in 2050. Production of steam from district heating units consequently decreases over time. Industrial boilers and industrial CHP plants decrease only slightly over the projection period due to increasing efficiency their steam output increases slightly.

[29] The modelling results for the statistical year 2010 appear to be lower than the corresponding published data from ENTSO-E. This is attributed to the limited time resolution of the load curves assumed in the model. The figures in Table 5 should be read as an indication of the trend that trade flows will follow, rather than as projections of their absolute level.

In terms of district heating fuel input, the share of solids and oil decreases considerably and the share of gas decreases as well but at a slower rate and only till 2030. Biomass is used increasingly representing almost 50% of fuel input in 2020 and 57% in 2050 (in comparison to 26% in 2010).

FIGURE 32: FUEL INPUT FOR STEAM GENERATION



Electricity costs and prices

The developments in the EU28 power sector have significant impacts on energy costs and electricity prices, in particular in the short term. Power generation costs significantly increase by 2020 relative to 2010, mainly as a consequence of higher investments due to the need for significant capital replacement and higher fuel costs (because of the large increase in international fossil fuel prices). Grid costs also increase to recover high investment costs in grid reinforcements and interconnectors, which are fully consistent with the provisions of the ENTSO-E TYNDP as well as the achievement of the RES 2020 target. Smaller components of the cost increase are national taxes and ETS allowance expenditures. In addition, there are the arithmetic effects of successful energy efficiency policies, which through curtailing

electricity demand reduce the denominator for sharing out the electricity costs while the numerator is less affected due to the high share of fixed costs in electricity generation and supply. As a result, average electricity price in the period 2010-20 increases by 31% (Table 7).

TABLE 7: EVOLUTION OF COST COMPONENTS OF ELECTRICITY PRICE IN 2010-20

€/MWh	diff. 2010-20	% contribution
Fixed and capital costs	14.2	34.5
Variable and fuel costs	4.5	11.1
Tax on fuels and ETS payments	3.8	9.1
Transmission, distribution and sales costs	7.5	18.3
Other costs (imports, recovery for RES*)	8.4	20.6
Excise and VAT taxes	2.6	6.4
Average price of electricity for final demand sectors (after tax)	41.0	

*RES supporting costs passed on to consumers

FIGURE 33: COST COMPONENTS OF AVERAGE ELECTRICITY PRICE

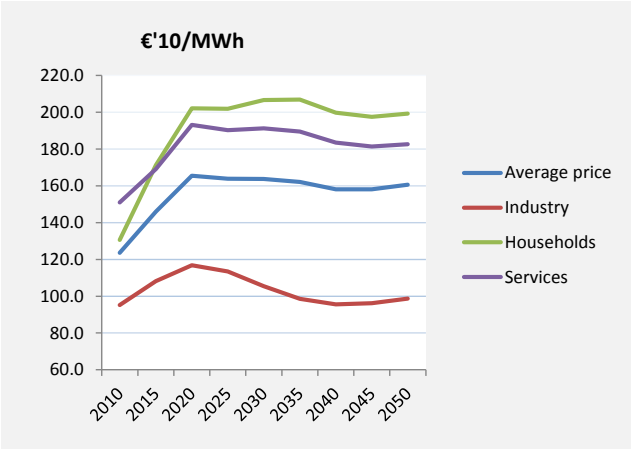
Average price of electricity (after tax)	131	172	172	169

FIGURE 34: PRICE OF ELECTRICITY (PRE-TAX) BY SECTOR



Beyond 2020, average electricity prices remain broadly stable up to 2035 and then are projected to moderately decrease up to 2050 (Figure 33 and Figure 34), as the benefits, in terms of fuel cost savings, resulting from the enormous restructuring invest-

Calculation of electricity prices in PRIMES

The electricity prices in PRIMES are calculated in order to recuperate all costs including those related to renewables including feed-in-tariffs, grid costs, and investment costs including stranded investments, back-up and reserve costs, etc., and including some profit margin.

The process to determine the electricity prices in PRIMES can be divided into four steps:

i) Determination of total system costs under least cost unit commitment and least cost expansion conditions mimicking well-functioning markets. ii) Simulation of wholesale markets by country and estimation of marginal system prices reflecting long run marginal costs. iii) Matching of load profiles of customer-types with the duration curve of long term marginal prices with customers sorted in descending order of their load factor mimicking bilateral contracting. iv) Calculation of prices by sector based on price levels by customer type calculated in step (iii) and the recovery of total system budget including variable generation costs and annuity payments for capital costs, recovery of additional costs for RES and cost of grid differentiated by voltage type.

Grid cost recovery is based exclusively on load payments at average grid tariffs determined as levelised costs of regulated asset basis.

The pricing approach corresponds to the Ramsey-Boiteux methodology and allows for the differentiation of electricity prices by sector.

ments in electricity supply come increasingly to the fore. In addition, lower technology costs from technology progress and learning over time help contain electricity prices together with deceleration of gas price increase.

Over time, the structure of costs slightly changes; capital intensive investments (RES and CCS) and increasing grid costs bring a decrease of the share of variable cost components and a corresponding increase in the capital cost components.

Primary energy supply and import dependency

The trend in total primary energy supply is downward throughout the projection period, with a moderate increase after 2035; energy efficiency gains in final energy demand are the main factors behind this trend. In parallel, there is a shift in primary energy supply towards RES along with a decline in the supply of solid fuels as well as oil (Figure 35). Natural gas maintains an almost stable share in primary energy supply throughout the projection period. Nuclear energy sees a decline in the short term (attributable to the nuclear phase-out that is being pursued by some Member States) but is projected to resume a moderate increasing trend in the decades after 2020.

Recovery from the economic crisis brings an upward effect on energy demand, observed up to 2015, which is consequently reflected on primary supply and import dependence (mainly for natural gas and solids). This trend is reversed until 2020, as the shift towards the consumption of RES in parallel with the improvements in energy efficiency (which lowers the demand) have a positive effect on import dependency (Figure 37). Evolution of primary energy production follows the declining trend of primary energy supply, it is however steeper and continuous throughout the projection period (with a small increase in the period 2035-45), as it reflects the depletion of domestic fossil fuel reserves. The mix in primary energy production changes considerably over time, with RES (including biomass) becoming the dominant energy form (Figure 36).

FIGURE 35: PRIMARY ENERGY SUPPLY

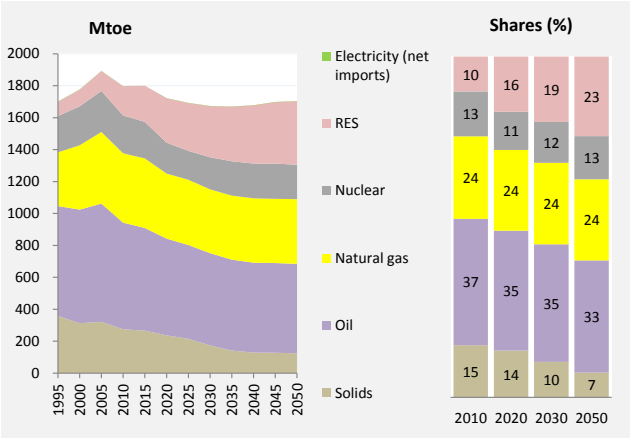


FIGURE 36: PRIMARY ENERGY PRODUCTION

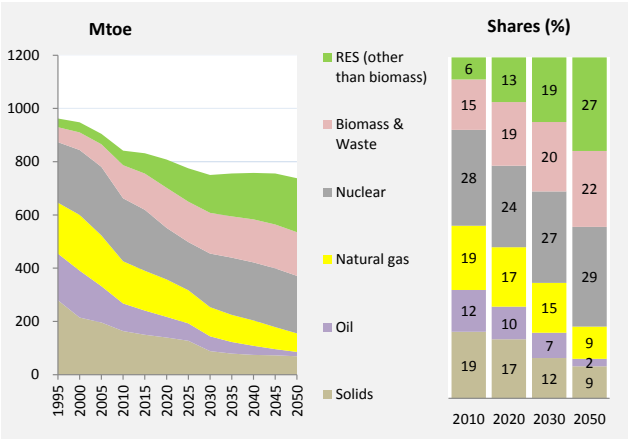

The situation in imports evolves only moderately. Beyond 2020, despite the decreasing trend in final energy demand for fossil fuels, limited domestic resources result in an increase in imports of natural gas and oil products (Figure 38), which drive net imports as well as import dependence moderately upward. By 2030, import dependence reaches 55%, and by 2050 it is close to 57%.

FIGURE 37: PRIMARY ENERGY IMPORTS

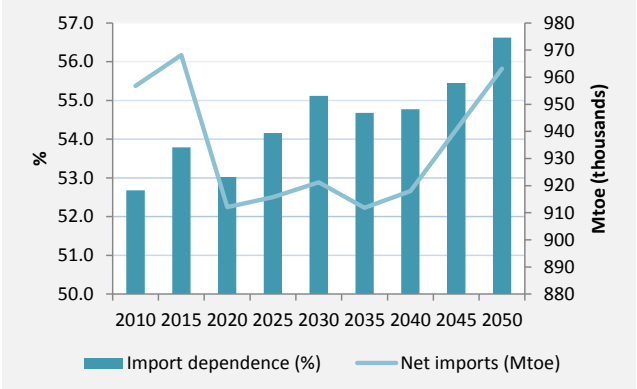

FIGURE 38: NET IMPORTS BY FUEL

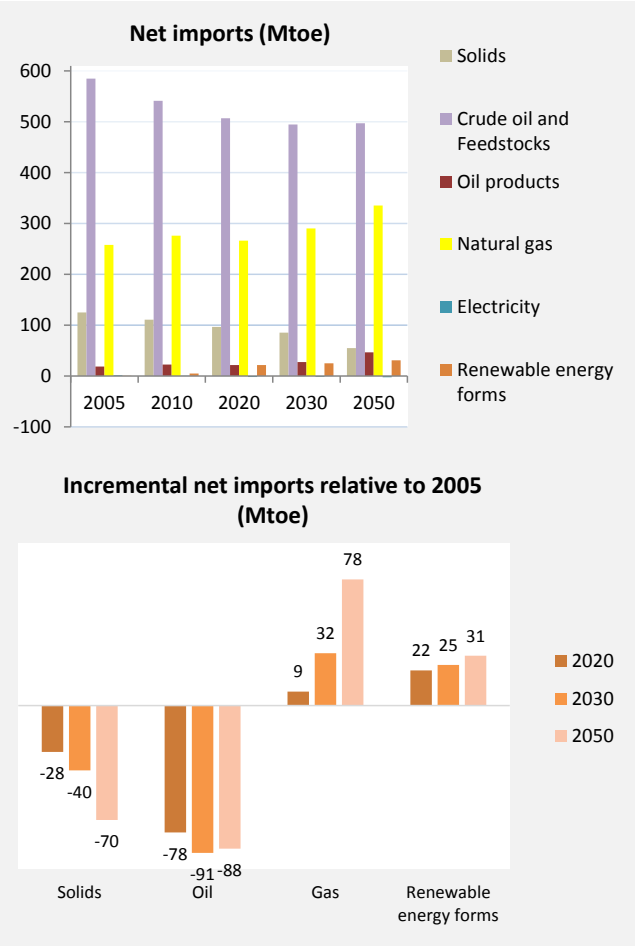


The external fossil fuel bill of the EU is projected to rise in constant prices by around 50% from 2010 to 2030 and exceeds 2010 levels by around 80% in 2050, reaching around 500 bn €'10 and 600 bn €'10 in 2030 and 2050, respectively.

Biomass supply, which is projected to be mostly indigenous in the EU, increases significantly over time following the developments of domestic industry which is increasingly using advanced feedstock and technologies. Until 2020, the increase in the demand for biofuels is faster than the growth of the domestic production, resulting in a substantial increase in the share of imported biofuels relative to past levels. Beyond 2020, domestic production catches up, and the share of imported biofuels remains stable until the end of the projection period.

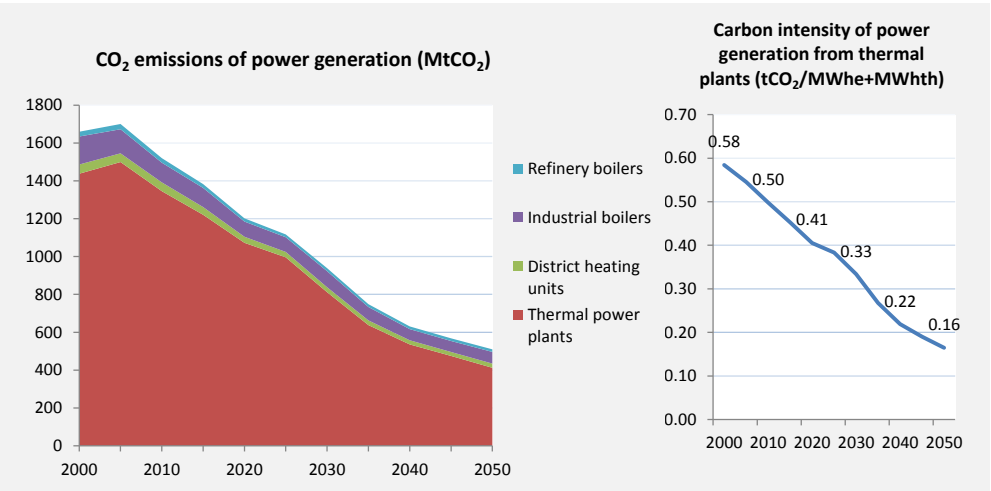
CO_2 emissions

The developments in the EU according to the Reference scenario energy projections that have been described so far, following the provisions of the EU ETS, the RES Directive, the ESD, the EED and other specific policies, result in reduced energy intensity of activities in parallel with reduced carbon intensity of power generation and energy demand. The combined effect of these developments is that CO_2 emissions in the EU are projected to decrease continuously until 2050. CO_2 emissions reduction is very significant, in particular in the power generation sector, resulting mainly from the ETS, in particular in the longer term. In other sectors, CO_2 emissions reduction is mainly driven by the energy intensity decreases that are induced by policies on energy efficiency.

The evolution of the generation mix implies a steady decrease in carbon intensity of power generation (Figure 39) and leads to significant emissions reductions from the sector. Carbon intensity of power generation from thermal plants decreases by 26% in 2020 relative to 2005. The corresponding figure in 2050 is 70%.

A significant factor of emissions reduction in power generation is the higher CHP market penetration and the increasing use of biomass in cogeneration, which

FIGURE 39: CO_2 EMISSIONS OF POWER GENERATION AND ENERGY TRANSFORMATION



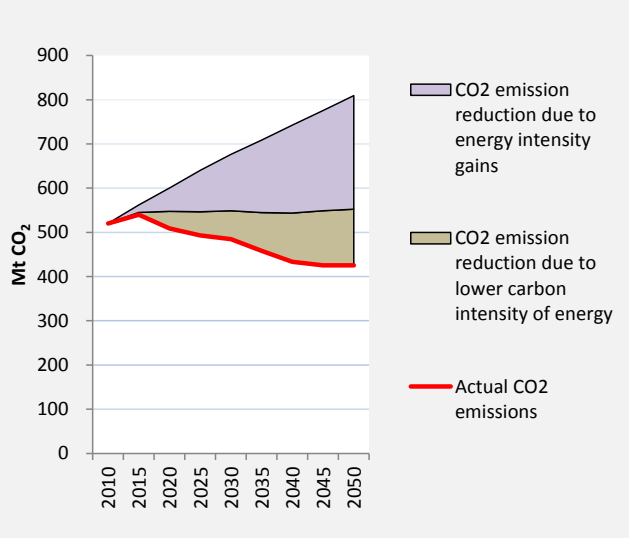
make steam generation less carbon intensive over time. In the longer term, the introduction of CCS technologies contributes to further emissions reduction; in 2030 the share of total CO_2 emissions from power generation that are captured is small, being slightly higher than 1%, however it is projected to rise to 48% of the remaining low emission level by 2050. Overall, in 2020, total CO_2 emissions of power generation are reduced by 29% relative to 2005; by 2030 and 2050, total emissions reduce by 45% and 70% respectively.

Also in the industrial sector, the ETS drives a shift towards less carbon intensive fuels, for both energy related and process related uses. In parallel, activity of the sector is projected to grow faster for non-energy intensive industries. Industry as a whole is also expected to make substantial efforts on energy efficiency as it is confronted with the increasing energy prices and the global competition.

The resulting effect on energy-related carbon intensity of the industrial sector is a 14% decrease by 2020 relative to 2005, which is projected to reach 19% until 2030 and 29% until 2050. As demonstrated in Figure 40: Energy-related CO2 emissions of the industrial sector

the impact of energy intensity decreases is driving the bulk of achieved emissions reduction.

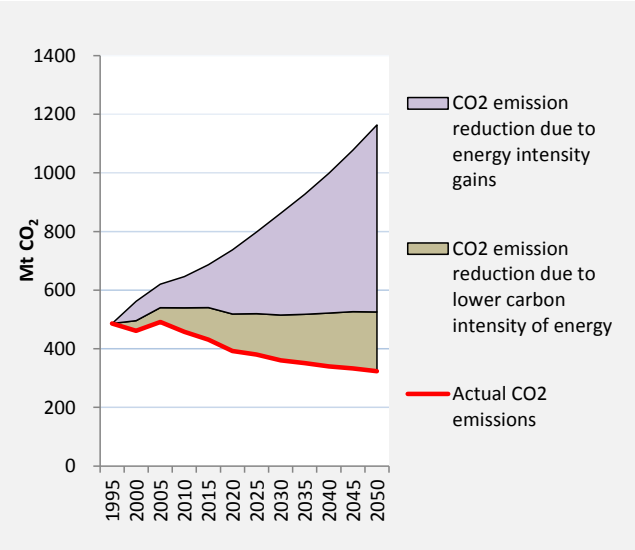
FIGURE 40: ENERGY-RELATED CO_2 EMISSIONS OF THE INDUSTRIAL SECTOR



Process related emissions[30] decrease only slightly in the short term (2% reduction in 2020 relative to 2005) but decrease becomes considerable in the long term (15% reduction in 2030), especially in the last decade of the projection (69% reduction in 2050) following the increasing trends of ETS prices, which make CCS for industrial processes an economically viable option.

The effect on emissions from energy intensity decrease is even more considerable for the residential sector (Figure 41), driven by increasing international fuel prices and policies on eco-design and performance of buildings, including the EED. The effect of these policies, in combination with renewables policies and national specific policies on reducing pollutants (thus driving a shift towards less carbon intensive fuels), drives a decrease of carbon intensity of the sector by 17%, 23% and 32% relative to 2005 in 2020, 2030 and 2050 respectively.

FIGURE 41: CO_2 EMISSIONS OF THE RESIDENTIAL SECTOR

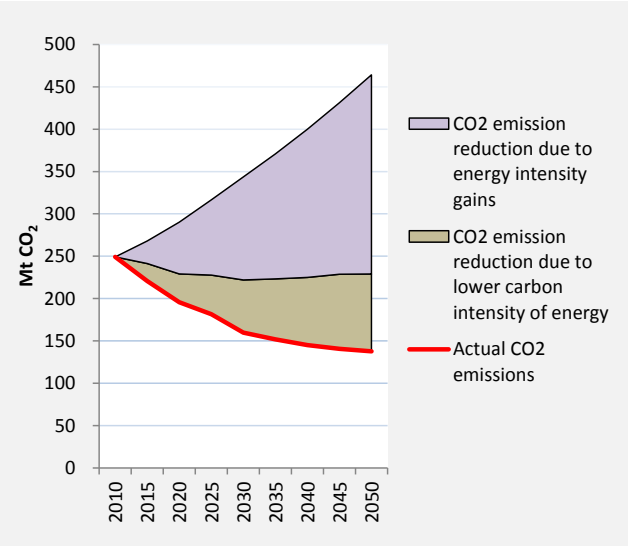


Similarly, in the tertiary sector (Figure 42), a significant progress occurs in terms of energy intensity decrease driven by rising fuel prices and energy efficiency policies, with projections showing a shift toward less carbon intensive fuels and electricity. Overall emissions decrease substantially throughout the projection period, achieving carbon intensity re-

[30] These include also the small amount of CO_2 emissions in the fugitive, solvent and waste sectors.

duction of 24%, 36% and 46% relative to 2005 in 2020, 2030 and 2050 respectively.

FIGURE 42: CO_2 EMISSIONS OF THE TERTIARY SECTOR

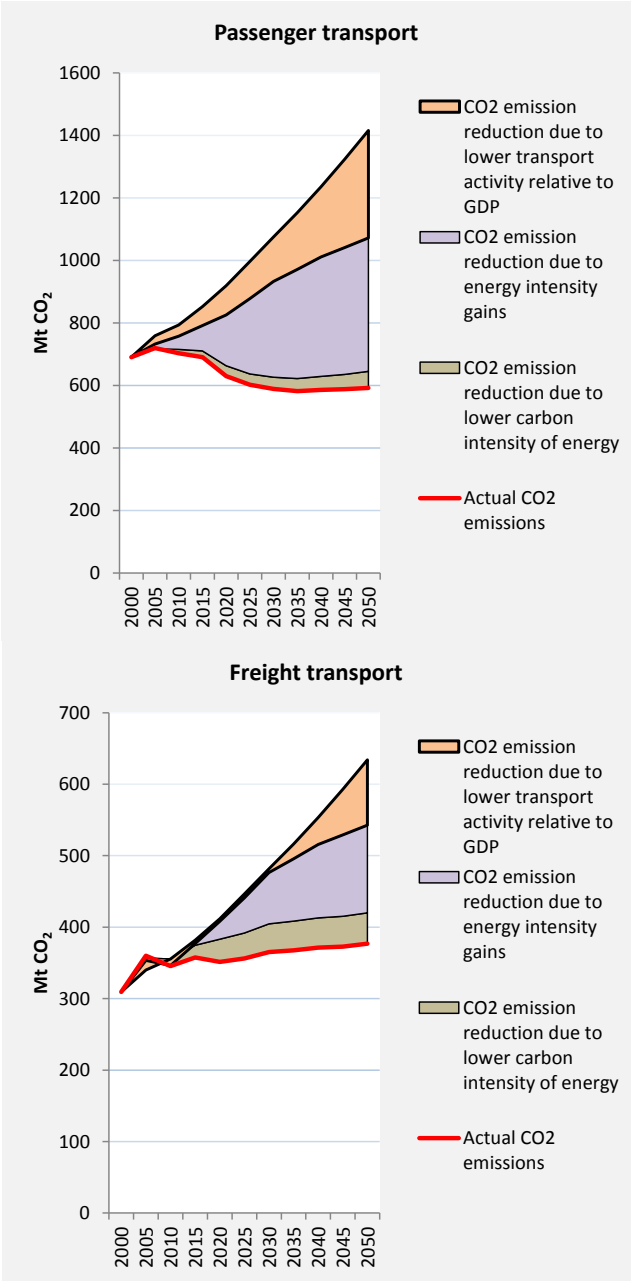


In transport, CO_2 emissions (excluding international maritime) go down by 8% between 2010 and 2050. CO_2 emissions decrease until 2035 and slightly increase thereafter primarily driven by CO_2 emissions growth in freight road transport and aviation (Figure 43). Fuel efficiency gains driven by CO_2 standards for LDVs as well as the increasing fossil fuel prices result in significant emission reductions relative to current trends. Decreases in carbon intensity of energy consumption are less pronounced as the projections do not show a significant shift towards alternative fuels. A shift to alternative fuels, including electricity, is mainly projected in the longer run for the passenger cars segment and in rail.

The main drivers of declining emissions are policies on CO_2 emissions from LDVs. These bring about a considerable decrease in emissions from passenger cars and light commercial vehicles, with the highest reduction taking place in the period 2010-20. Beyond 2035, CO_2 emissions from passenger road transport stabilize with no further tightening of CO_2 standards assumed.

Aviation emissions are increasing over the projection period, however at a slower rate than aviation activity, primarily due to the fuel efficiency improvements and the slow penetration of bio-kerosene beyond 2035, fostered by rising ETS prices. CO_2 emissions from passenger rail are decreasing as a result of switching from diesel to electricity and the shift from conventional passenger rail to high-speed rail.

FIGURE 43: CO_2 EMISSIONS OF THE TRANSPORT SECTOR



Regarding freight transport, CO_2 emissions steadily grow throughout the projection period. The main contributor to CO_2 emissions growth is road freight, where the increased activity surpasses improvements in specific fuel consumption, especially for HGVs. CO_2 emissions from other modes (rail and inland navigation) hold a small share in total freight emissions.

Figure 44 and Figure 45 depict the evolution of total CO_2 emissions and indicate two main characteristics[31]; the first one is that dedicated policies result in ETS CO_2 emissions reducing faster than overall emissions. Moreover, the trend in CO_2 emissions shows a very steep decrease in power generation, whereas emissions in the field of transport increase compared to 1990 and decrease at much slower pace between 2010 and 2050 due to the relatively high marginal abatement costs in this sector. In the long term, as power generation becomes almost completely carbon-free, the transport sector becomes the largest source of CO_2 emissions.

FIGURE 44: EVOLUTION OF CO_2 EMISSIONS

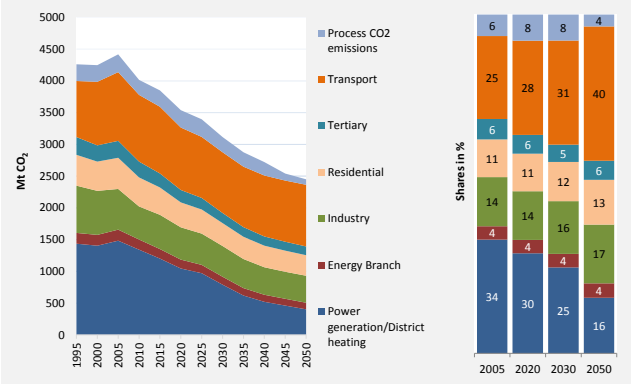
FIGURE 45: EVOLUTION OF CO_2 EMISSIONS BY SECTOR



Non-CO_2 emissions and their drivers

Current and future emissions of anthropogenic non-CO_2 greenhouse gases (GHGs) have been estimated for the Reference scenario using the GAINS model. The input of energy activity drivers was taken from PRIMES model results and agricultural activity drivers were derived from CAPRI model results (see box on the next page). Drivers for other relevant sectors (e.g., waste and F-gases) were developed within the GAINS model to be consistent with the macroeconomic projections as described in section 2. The non-CO_2 GHGs considered here are the ones targeted under the Kyoto protocol, i.e. methane (CH_4), nitrous oxide (N_2O) and three groups of fluorinated gases (F-gases) viz. hydrofluorocarbons (HFCs), perfluorocarbons (PFCs) and sulphur hexafluoride (SF_6). Emissions of non-CO_2 GHGs have been expressed in terms of Mt CO_2eq adopting IPCC AR2 Global Warming Potentials (GWPs) over 100 years, i.e. on a weight-equivalent basis the CO_2 equivalent warming potential adopted for CH_4 is 21 (i.e. 1t CH_4 equals 21t CO_2eq), for N_2O it is 310 (i.e. 1t N_2O equals 310t CO_2eq) and for the different F-gases have a GWP which ranges between 140 and 23900 depending on the F-gas. The GAINS model estimates for CH_4 and N_2O emissions in year 2005 are aligned with the emissions reported by Member States to the UNFCCC (as of April 2012) by introducing country- and gas specific calibration residuals. These carry over as constants to all future years. The constants reflect differences in the methodological approaches taken by countries relative to the consistent GAINS model approach, as well as minor emission sources which countries report that are not captured in the GAINS

[31] For consistency reasons PRIMES calculates energy-related CO_2 emissions based on the fuel use reported in Eurostat energy balances and projected in PRIMES. The calculated emissions may therefore vary from energy-related CO_2 emissions reported to UNFCCC. Process related and other CO_2 emissions are projected starting from the emission inventories for 2005 and 2010 as reported to the UNFCCC in May 2012. Starting from this basis, PRIMES total CO_2 emissions are calibrated to total CO_2 emissions reported to UNFCCC in 2012 for 2005 to the extent reasonably possible. In particular, adjustments have been done for process-related emissions to avoid possible double counting of CO_2 emissions. PRIMES ETS sector coverage corresponds to the phase 3 ETS scope as valid since 2013. ETS emissions are calibrated to 2005 and 2010 ETS CO_2 emissions, with higher importance accorded to calibration for 2005, based on verified emissions and estimates for scope adjustments and additional sectors.

model structure[32]. No calibration was conducted for F-gas emissions, because of large variation between countries in the quality and completeness of the reported emissions.

Non-CO_2 GHGs are emitted from a variety of sources and sectors. Figure 46 shows the contribution of the major sectors to total non-CO_2 emissions in 2005 and the projected development to 2050 in the Reference scenario. Non-CO_2 GHG emissions in EU28 are expected to decline from 903 to 728 Mt CO_2eq between 2005 and 2030 and stabilize on that level throughout the remaining projection period. The agricultural sector is a major contributor to emissions, responsible for over 50% in 2005 and with only minimal decline expected in the future. The largest decline in emissions is expected to take place in the waste and industry sectors in response to existing control regulations.

FIGURE 46: NON-CO_2 GHGS BY MAJOR SECTORS IN EU28 2005 TO 2050

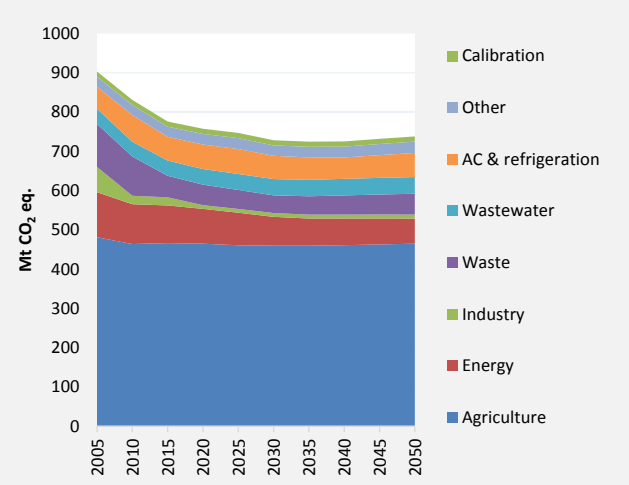


Table 8 provides an overview of the main national policies affecting the Reference scenario non-CO2 GHG emissions projections in EU28. The relevant EU level policies (see overview table in section 1.3) are in particular the EU Landfill Directive and the EU F-gas regulation, as well as the EU ETS. In the following sections, the emission projections are described by sector and in more detail - explaining drivers, current control and reasons for overall trends.

The Greenhouse Gas and Air Pollution Interactions and Synergies (GAINS) model is an integrated assessment model developed by the International Institute for Applied Systems Analysis (IIASA) for the purpose of describing policy-relevant pathways of atmospheric pollution from anthropogenic sources. Greenhouse gases (GHGs) and many of the traditional air pollutants have common sources, their emissions interact in the atmosphere, and separately or jointly they cause a variety of environmental effects at the local, regional and global scales. The GAINS model addresses emission control strategies that simultaneously address air pollutants and greenhouse gases.

The GAINS model was used to produce projections of EU28 non-CO_2 GHG emissions. The model includes information on emission factors, technical control potentials and costs which when combined with economic, energy and agricultural activity pathways from the PRIMES and CAPRI models, result in consistent projections of future non-CO_2 GHGs.

The Common Agricultural Policy Regional Impact (CAPRI) model is an agricultural sector model with a focus on Europe (disaggregation into 280 NUTS2 regions, detailed activity data and coverage of Common Agricultural policies), but embedded in a global market model to represent bilateral trade between 44 regions (countries or country aggregates). The main model outputs are market balance data, prices, income and economic welfare and, due to its high level of disaggregation in the activity data, also various environmental indicators like nutrient balances, erosion etc. (see www.capri-model.org).

The CAPRI outlook systematically merges the information in historical time series with external projections from other models or independent expert knowledge while imposing technical consistency. Key external information came from the models PRIMES, GLOBIOM and AGLINK, together with national expert information on specific items. The key outputs (to GAINS) were the activity data in the livestock sector plus mineral fertilizer use in the crop sector.

[32] A detailed description of the GAINS methodology for estimating non-CO_2 GHGs and projections for EU28 can be found in Höglund-Isaksson, L., W. Winiwarter, P. Purohit: Non-CO2 greenhouse gas emissions, mitigation potentials and costs in EU28 from 2005 to 2050, Part I: GAINS model methodology, International Institute for Applied Systems Analysis, Laxenburg, Austria.

TABLE 8 : MAIN NATIONAL POLICIES WITH SPECIFIC EFFECTS ON NON-CO_2 GHGS AND CONSIDERED IN THE REFERENCE SCENARIO

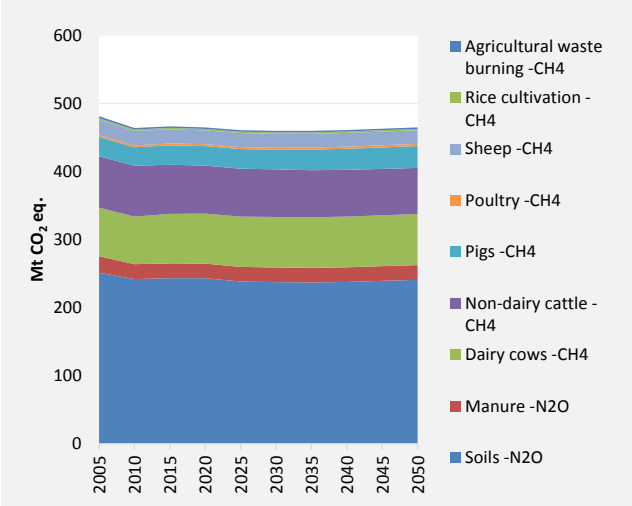
National policies		
1	Ban on landfill of biodegradable waste	Austria, Belgium, Denmark, Germany, Netherlands, Sweden
2	National F-gas policies	Austria, Belgium, Denmark, Germany, Netherlands, Sweden
3	Subsidy scheme for anaerobic digestion of manure	Netherlands

Decomposing non-CO_2 GHG emissions for the ETS and the non-ETS sectors reveals different trends for the two categories. Emissions from the ETS sectors demonstrate a very significant decrease as they fall 90% from 2005 already by 2020 and slightly decrease thereafter (see section on industry sectors below). These constitute however a small share of overall non-CO_2 GHGs (6% in 2005). The reduction of emissions of gases from the non-ETS sectors is less pronounced. In 2020 the reduction achieved is 11% relative to 2005. The trend continues to be decreasing reaching a 15% reduction in 2030. Beyond 2035, the trend is reversed and ultimately in 2050 the reduction relative to 2005 is projected to be 13%.

Agriculture sector

The main source of agricultural non-CO_2 GHGs are N_2O emissions from microbial processes in soils. They contribute to roughly half of agricultural non-CO_2 GHGs in EU28, as shown in Figure 47. The activity driver for soil emissions used in GAINS is nitrogen input on agricultural lands, which is the sum of the nitrogen contained in mineral fertilizers applied, animal manure spread and crop residues left on fields. Activity numbers used are Eurostat data, while future trends in mineral fertilizer input on lands and animal numbers are adopted from projections made by the CAPRI model. Country-specific information on crop residues and animal excretion rates are taken from national reporting to the UNFCCC (2012) and kept constant over time. N_2O emissions from soils are estimated at 251 Mt CO_2eq in 2005 with a slight decline of 5 percent to 2030 due to declining trends in mineral fertilizer use and cattle numbers (see Figure 47).

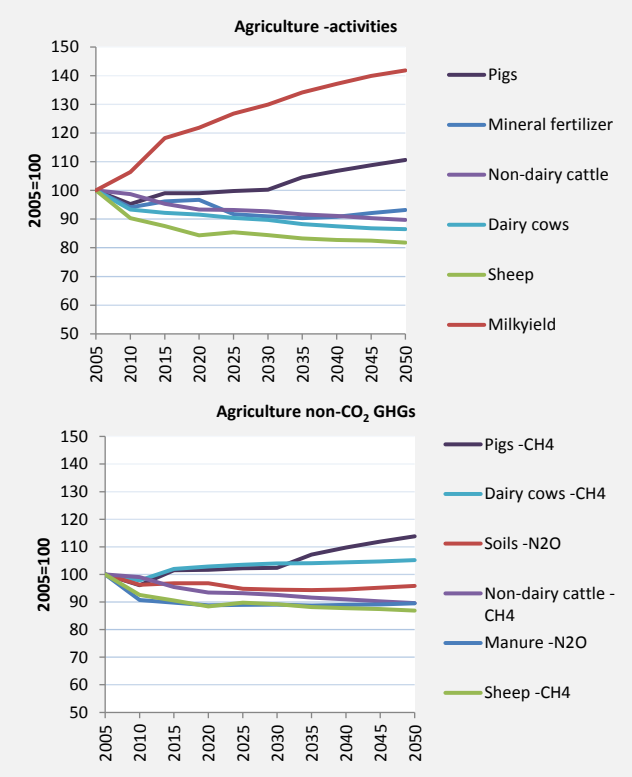
FIGURE 47: NON-CO_2 GHGS OF THE AGRICULTURE SECTOR IN EU28 BY SOURCE



The other major source of agricultural non-CO_2 GHGs is livestock rearing (dairy and non-dairy cattle, pigs, sheep and poultry) and accounts for 225 Mt CO_2eq in 2005 with a slight expected decline to 218 Mt CO_2eq in 2030. CH_4 emissions are released from enteric fermentation in ruminants as well as management of animal manure, which gives rise to anaerobic conditions during which microbial activity forms N_2O and CH_4 which are then released. Enteric fermentation and manure management emissions from dairy cows are driven by the development in animal numbers as well as by changes in metabolic activity: more productive cows (productivity expressed as milk yield per cow) tend to cause higher emissions per animal. The increase in CH_4 emissions from dairy cows in Figure 48 results from an increased milk production and the combined effect of a 10 percent decline in animal numbers and a 30 percent expected increase in the average milk yield per cow between 2005 and 2030.

For other animal categories, emissions are almost exclusively driven by animal numbers. CH_4 emissions mainly from large pig farms are about 2 Mt CO_2eq per year lower than would be expected on the basis of activity levels only due to the existing capacity to treat manure in anaerobic digesters with energy recovery. This is the result of national policies.

FIGURE 48: AGRICULTURE SECTOR ACTIVITY DRIVERS AND EMISSIONS OF NON-CO_2 GHGS IN EU28

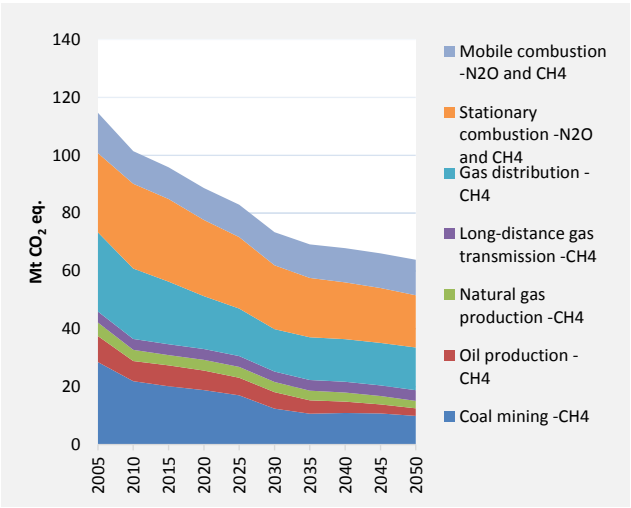


Energy sector

Energy sector sources of non-CO_2 GHGs are fugitive leakage of CH_4 from fossil fuel extraction and transportation and CH_4 and N_2O emissions from fuel combustion, as shown in Figure 49. N_2O from combustion sources is partly a direct by-product of combustion as well as has been a side-effect of some NO_x control technologies on stationary and mobile combustion sources[33]. Some low-NO_x technologies like fluidized bed combustion or selective NO_x reduction technologies reduce NO_x emissions but may strongly increase N_2O emissions. The relative decline in N_2O emissions from combustion is stronger than the expected decline in total energy consumption, which is the result of a fuel use shift in stationary sources away from fluidized bed combustion of fossil solid fuels. CH_4 emissions from extraction of coal, natural gas and oil decline in line with the expected reduction of fossil fuel production in the EU. The driver for the projected leakage from long-distance gas transmission is the gas consumption in the respective country. Leakage from this source does not decline proportionately with gas consumption due to a relatively stronger increase in demand in countries which report higher leakage rates. CH_4 leakage from consumer gas distribution networks declines faster than gas consumption due to effects of an on-going replacement of old town gas networks in some EU countries expected to be completed in 2030.

[33] Mobile combustion sources refer to combustion in the transport sector. For mobile sources, this problem seems to be solved with today's technologies.

FIGURE 49: NON-CO_2 GHGS OF THE ENERGY SECTOR IN EU28 BY SOURCE



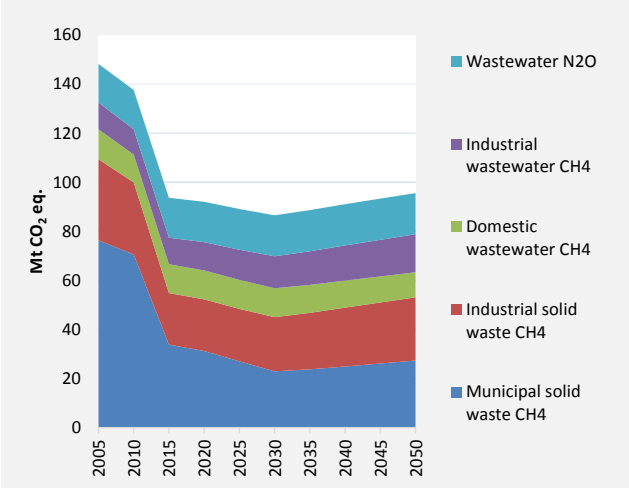
Waste and wastewater sector

In 2005, the waste and wastewater sectors in EU28 are estimated to have released almost 150 Mt CO_2eq. Half of this amount comes from municipal solid waste as shown in Figure 50. CH_4 from solid waste is released when biodegradable matter decomposes under anaerobic conditions in landfills or during storage and handling of biodegradable waste in different waste treatment processes. Due to the slow decomposition of waste in landfills, GAINS models future emissions as driven by the gross (pre-treatment) amounts of waste generated ten to twenty years before. Further parameters include the fraction of the waste deposited on landfills and the effect on emissions of current recovery and control of landfill gas. The gross amounts of solid waste generated are driven by GDP and urbanization rate for municipal solid waste and by value added in the relevant manufacturing industries. The implementation of the EU Landfill Directive is expected to reduce CH_4 emissions from municipal and industrial solid waste by almost 60 percent between 2005 and 2030. A modest decline in emissions of 9 percent between 2005 and

2010 result from landfill gas recovery becoming mandatory from 2009, while the deeper cuts in emissions between 2010 and 2030 are expected from the increased diversion of biodegradable waste away from landfills through separation and treatment. Taking into account the time lag between disposal and emission release from landfills, the full effect of the Landfill Directive on CH_4 emissions is achieved only in 2030. Thereafter emissions start rising slowly driven by the expected future growth in GDP and industry value added.

Wastewater from households and organic processes in industry contain nitrogen and organic compounds which wastewater treatment plants are decomposing before discharge. The main gaseous products are CO_2 and molecular nitrogen but during the process also CH_4 and N_2O are formed and released. Figure 50 shows that the release of CH_4 and N_2O from wastewater handling and treatment in EU28 is expected to remain at a level of about 40 Mt CO_2eq between 2005 and 2050. The activity driver for N2O emissions from wastewater is total population. Driver for CH_4 emissions from domestic wastewater is the number of people connected to centralised (urban) and decentralised (rural) collection of wastewater, respectively. The activity data used to estimate CH_4 emissions from industry wastewater is chemical oxygen demand (COD) in untreated wastewater from the manufacturing of food, pulp and paper, and organic chemical products. Projections of future emissions are driven by growth in value added in respective industry. The EU Urban Wastewater Treatment Directive regulates the release of waterborne pollutants in wastewater from urban households and food industry. “Appropriate treatment” must be in place by 2005. In GAINS, “appropriate treatment” is interpreted as a conversion from primary mechanical treatment to secondary/tertiary aerobic and/or anaerobic treatment. As a side-effect to improved water quality, such conversions also reduce the formation and release of CH_4. CH_4 emissions from domestic and industrial wastewater drop slightly between 2005 and 2010 primarily due to extensions of secondary/tertiary wastewater treatment in some new Member States but also as a result of more people being connected to centralized wastewater treatment. After 2030 CH_4 emissions from domestic wastewater treatment decline assuming that with the natural turnover of capital municipal wastewater treatment plants will become more effective in controlling CH_4 emissions. This assumption does not apply to the more small-scale treatment of industrial wastewater and therefore CH_4 emissions from industrial wastewater are expected to grow proportionately to value added in the relevant industries.

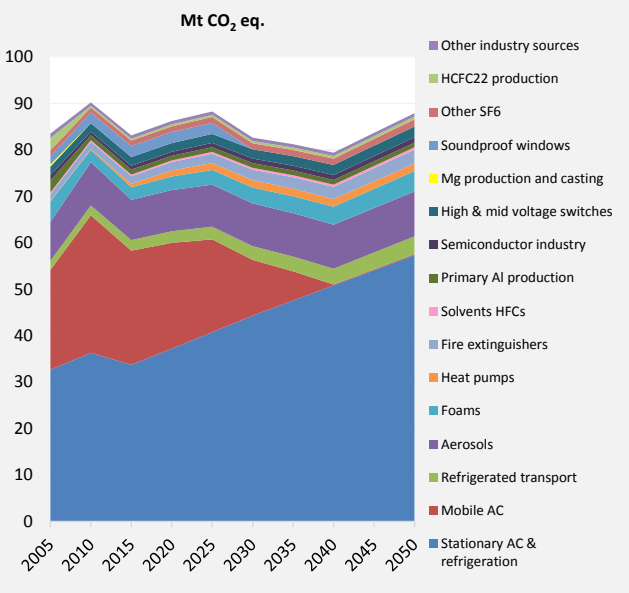
FIGURE 50: NON-CO_2 GHGS OF THE WASTE AND WASTEWATER SECTOR IN EU28



F-gas emissions

Emissions of fluorinated gases (F-gases) considered here are HFCs, PFCs and SF_6. HFCs are primarily used as cooling agent in air conditioners (AC) and refrigerators, but also as blowing agents in foams and propellants for aerosols. Sources of PFC emissions are primary aluminum production and semiconductor industry, while SF_6 serves a variety of uses in e.g., high and mid voltage switches, magnesium production and casting, soundproof windows, sports and military equipment. Although used in small quantities, the high warming potentials and long lifetimes in the atmosphere make the contribution of these gases to global warming significant in CO_2-eq terms. Figure 51 shows how F-gas emissions in EU28 are expected to fluctuate between 80 and 90 Mt CO_2eq over the period 2005 to 2050, which represents an increasing share of total non-CO_2 GHGs from 9 to 12 percent (due to the overall decline in CH_4 and N_2O emissions).

FIGURE 51: F-GAS EMISSIONS IN EU28 BY SOURCE

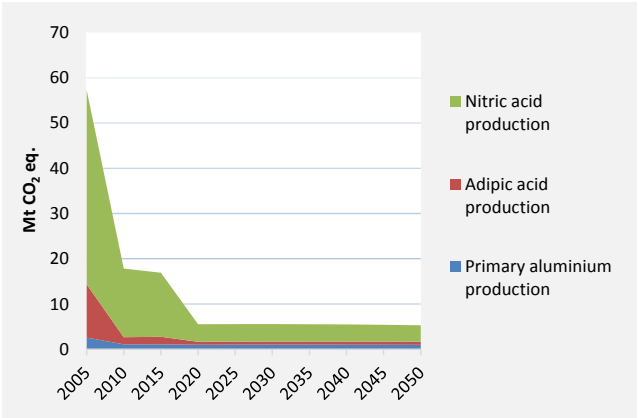


The fluctuating but relatively stable level of F-gas emissions is the combined result of a strong increase in demand for services offered by F-gases (e.g., cooling), replacement of the ozone-depleting substances CFCs and HCFCs with HFCs in order to comply with the Montreal Protocol, and effects of adopted regulations to control F-gas emissions. Demand for cooling and refrigeration in GAINS is primarily driven by economic growth along with cooling degree days, commercial floor space and assumptions about technology penetration and saturation rates[34] . The EU F-gas regulation came into effect in 2006 and the EU Directive on mobile air-conditioning systems in steps from 2008 onwards. Together with stricter national F-gas legislation in several member states (Austria, Belgium, Denmark, Germany, Netherlands and Sweden) these regulations account for the expected stabilization in future F-gas emissions after 2010 shown in Figure 51. The Reference projection does not take account of the ongoing revision of the EU F-gas regulation due to be adopted by 2014, aiming to significantly reduce emissions. Included in the Reference scenario is the prohibition of high GWP cooling agents in mobile air conditioners (MACs). It is assumed that the use of HFC-134a in MACs is replaced by HFO-1234yf with a GWP of 4 resulting in an almost complete phase-out of these emissions by 2040. The decline in F-gas emissions between 2010 and 2015 seen in Figure 51 is due to compliance with the EU F-gas regulation which requires leakage control and end-of-life recovery of HFCs from AC and refrigeration equipment, limitations on the use of F-gases as propellants for aerosols and foams and a ban on SF_6 use in various applications e.g., soundproof windows and sports equipment.

Industry sectors covered by the EU ETS

Emissions of non-CO_2 GHGs from sectors regulated under the EU Emissions Trading System (EU-ETS) since 2013 include N_2O emissions from nitric and adipic acid production and PFCs from primary aluminum production. In 2005 these emissions amounted to 57 Mt CO_2eq or 6 percent of total non-CO_2 GHGs in EU28. N_2O emissions from nitric and adipic acid production can be effectively controlled through installation of existing low cost technology. The marginal cost of these technologies is lower than the carbon price in the EU-ETS thereby making technology adoption profitable. This together with the anticipation of the ETS inclusion, related Joint Implementation projects and the economic crisis explain the sharp decline of 70 percent in reported emissions between 2005 and 2010 shown in Figure 52, as well as the further decline.

FIGURE 52: NON-CO_2 GHGS OF EU-ETS SECTORS IN EU28



By 2020 the expected decline in emissions is 90 percent due to full adoption of available and improved technologies. PFC emissions from primary aluminum production are linked to the use of older production technologies. With the natural turnover of capital the older technologies are expected to be replaced by the

[34] Please see Höglund-Isaksson et al. 2013 for details.

more efficient and less emitting point-feeder prebake (PFPB) technology.

Total GHG emissions (excluding LULUCF)

Overall, in 2020, the corresponding GHG emissions targets are projected to be overachieved; total reduction in GHG emissions relative to 1990 is 24%, resulting from 22% reduction of CO_2 emissions and 35% reduction of emissions from non-CO_2 gases. In the ETS sectors, total GHG emissions are reduced by 24% relative to 2005, surpassing the target of 21% due to the projected continuous build-up of an allowance surplus. Regarding non-ETS sectors, the target of the ESD is overachieved at the EU level, with total emissions reducing by 15% in 2020 relative to 2005, surpassing the 10% target. Respective national targets are achieved domestically in the majority of countries.

Until 2030, developments (in particular in the power sector) result in total GHG emissions reducing by 32% relative to 1990. Emissions of the ETS sectors reduce by 36% compared to 2005, with 47% being the corresponding figure for power generation alone. Non-ETS sectors also see a decrease in emissions but not as strong. Finally, in 2050 perspective, emissions continue to decrease, primarily driven by developments in power generation. Overall GHGs emissions are reduced by 44% relative to 1990 (46% for CO_2 emissions).

FIGURE 53: EVOLUTION OF GHG EMISSIONS[35]

	2005	2010	2015	2020	2025	2030	2035	2040	2045	2050
Non-ETS GHGs	2808	2667	2535	2383	2311	2238	2200	2176	2166	2165
ETS GHGs	2514	2180	2091	1913	1832	1606	1400	1271	1107	1024
Total GHGs	5322	4847	4626	4297	4142	3844	3601	3447	3273	3188

The decreasing trend in emissions beyond 2020 is well pronounced, especially for the power generation sector, however it is not sufficiently intense in order to achieve the long-term objectives in the context of the Roadmaps to 2050. More specifically, in line with the EU's objective of -80 to -95% GHG emissions reduction in 2050 compared to 1990, the Roadmap for moving to a low carbon economy in 2050[36] sets a milestone for GHG emissions reductions in the EU of 40% in 2030 relative to 1990 and 80% in 2050, while the projections in the Reference 2013 scenario are 32% reduction in 2030 and 44% reduction in 2050.

LULUCF emissions and removals and their drivers

Current and future CO_2 emissions from the land use, land use change and forestry sector (LULUCF) have been estimated using the Global Biosphere Management Model (GLOBIOM) and the Global Forest Model (G4M) models. Basic drivers, such as: GDP, population development, energy demand, biomass energy supply and productivity changes are generated by PRIMES and GEM-E3 or provided by global databases[37]. These drivers are then used by the economic bottom-up land use model GLOBIOM. Demand is endogenously produced by the model and matched by supply of food, fodder, timber and energy. The information between models flows not only in one direction but is circulated between GLOBIOM and G4M models iteratively, where relevant. While G4M is used to estimate emissions from forest land, GLOBIOM estimates emissions from crop- and grassland. Remaining emissions from wetlands, settlements and other land (corresponding to UNFCCC accounts) are not modeled explicitly and kept constant at 2010 levels until 2050.

Table 9 gives a brief overview of the datasets and models used to estimate LULUCF areas and emission factors.

The EU28 LULUCF sector is at present a carbon sink as it sequesters more carbon than it emits. The EU LULUCF sink in the UNFCCC inventory was estimated between 288 Mt CO_2 in 2000 and 296 Mt CO_2 in 2010[38] which is around 20% above the projections

[35] Excluding LULUCF emissions and removals. For comparability reasons over time, ETS and non-ETS emissions for 2005 and 2010 are reported in ETS phase 3 scope as valid from 2013.

[36] COM(2011)112

[37] DG ECFIN publications are used for macro-economic projections.

[38] Please see: http://unfccc.int.

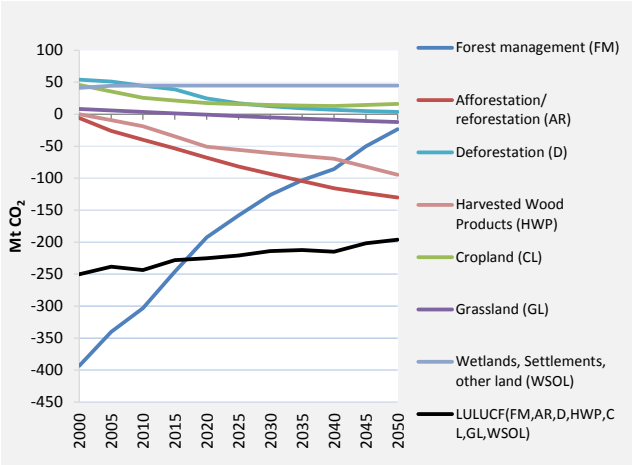
delivered by GLOBIOM and G4M. The difference is related to model and datasets uncertainties as well as different modeling and reporting approaches applied. The LULUCF sink is expected to be maintained until 2050, even though it is projected to decline from about -244 Mt CO_2 in 2010, to -214 Mt CO_2 in 2030 and -196 Mt CO_2 in 2050 in the Reference scenario, which corresponds to a decrease from 2010 levels of -12% by 2030 and -20% by 2050. This decline is the result of changes in different land use activities of which the forest sector changes are the most important. Figure 54 shows the projection of the total EU28 LULUCF sink in the Reference scenario until 2050 and the contribution from different activities.

TABLE 9: METHODOLOGY USED TO ESTIMATE LULUCF EMISSIONS

	Area/Supply estimate	Emission factor
Afforestation	G4M estimate, based on GLOBIOM drivers, calibrated to historic level (UNFCCC)	Internal forest growth model, simplified soil emission estimate based on literature
Deforestation	G4M estimate, based on GLOBIOM drivers, calibrated to historic level (UNFCCC)	Average biomass stock estimated by G4M, based on remote sensing map
Forest management	Based on country UNFCCC and Kyoto data or other data bases (MCPFE)	G4M estimate based on age class structure, initial biomass stock, management regime etc.
Cropland management	GLOBIOM estimate, calibrated to historic level (EUROSTAT)	Estimate of biophysical crop model (EPIC), depending on soil, climate and crop parameters
Grassland management	GLOBIOM estimate, calibrated to historic level (EUROSTAT)	Country level emission factor based on UNFCCC data
Settlements, wetlands and other land	UNFCCC data	UNFCCC data
Harvested wood products	GLOBIOM estimate, calibrated to historic level (FAO, country submission)	IPCC default values

In general, forest management emissions are driven by the balance of harvest removals and forest increment rates (the growth of the biomass stored in a forest as a result of the growth of the trees with the age). As harvesting removals increase over time related to growing demand for wood for products (such as furniture or paper), the carbon sink in managed forests declines significantly. Growing demand for wood as projected by GLOBIOM is driven by population and income growth as well as increasing wood demand for renewable energy production. The significant decline in the managed forests carbon sink can however be partially compensated by a rising carbon sink from afforestation, a decrease in deforestation and increasing carbon storage in harvested wood product. Since part of the harvested biomass is processed to final wood products which have a lifespan of several years, the carbon sink from harvested wood products increases (see Figure 54). Until 2050, emissions from deforestation continue to decrease in line with historic trends. In addition, carbon sequestration from afforested areas increases due to that fact that new forests are established but also young forests that were established over the last 20 years get into a phase of high biomass production.

FIGURE 54: EU28 LULUCF EMISSIONS UNTIL 2050 IN MT CO_2

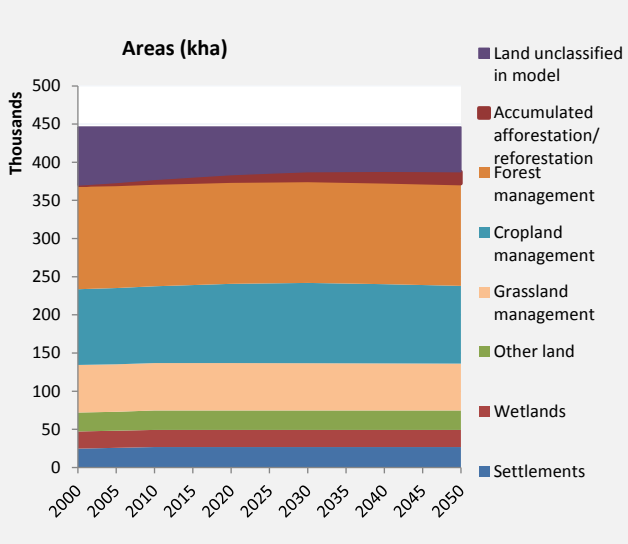


Activities in the agricultural sector have a smaller impact on the total LULUCF sink compared to the forest sector. Still, net carbon emissions from cropland are projected to decline by some 40% compared to 2010 due to the increasing cultivation of annual (e.g. miscanthus, switchgrass) and perennial lignocellulosic

crops (e.g. short rotation tree plantations) for renewable biomass based bioenergy production. Typically these plants provide more litter input into the soil and management activities are less disturbing the soil, leading to a reduced loss or even an accumulation of soil carbon. Similarly, total emissions from grasslands are expected to go down as more land is projected to be converted to grassland that typically tends to sequester additional carbon.

Figure 55 shows the EU28 LULUCF sector land balance until 2050. Over time, the forest area expands by 4% in 2030 and 7% in 2050 compared to 2010 at the expense of cropland and grassland taken out of production. Cropland and grassland areas remain at more or less constant levels. The area for perennial crops (including annual lignocellulosic crops) for renewable energy production grows significantly and by 2030 7% of total cropland is cultivated with perennials (9% in 2050).

FIGURE 55: EU28 LULUCF SECTOR LAND BALANCE IN 1.000 HA UNTIL 2050



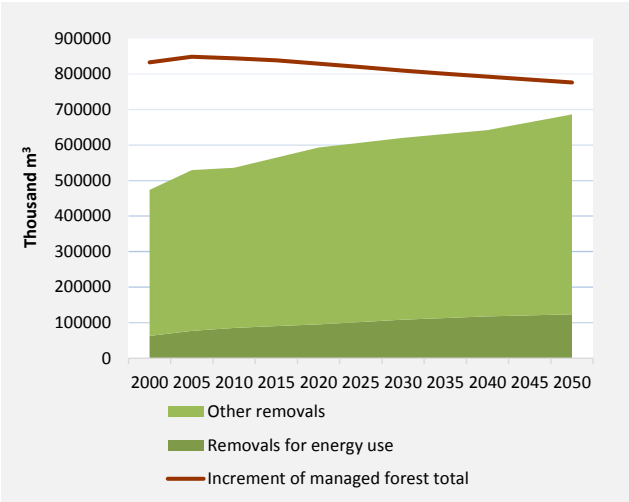
The following sections provide a more detailed overview of the drivers, emission projections and overall trends by the different LULUCF sectors.

Emissions from forest land

The current net forest sink (the sum of forest management, afforestation and deforestation) is projected to decrease from -299 Mt CO_2 in 2010, to -208 Mt CO_2 in 2030 and -150 Mt CO_2 in 2050 which corresponds to a decline by -31% and -50% in 2030 and 2050, respectively. This is the result of different, partly, opposing trends. Increasing wood demand and corresponding rising harvesting removals are important drivers, but also a projected decline in the forest growth rate due to ageing. Harvesting removals rise from 536 million m^3 in 2010, to 620 million m^3 in 2030 and 686 million m^3 in 2050. At the same time, the carbon sink in managed forests declines from -303 Mt CO_2 in 2010 to -127 Mt CO_2 in 2030 and -24 Mt CO_2 in 2050.

Total harvest removals in EU28 increase steadily over time as well as the share wood removed for energy use in the total harvest (see Figure 56). This share increases from 16% of total harvest in 2010, to 17% in 2030 and 18% in 2050 as demand for renewable energy production rises. Despite a decrease of forest increment over time, in 2050 the increment is with 777 million m^3 still well above the total wood removals which sum up to 686 million m^3. Reasons for the declining forest increment are a change in age class structure towards a higher share of older forest stands that grow at lower rates and a saturation of biomass accumulation. European forests get older but also thicker and therefore grow relatively slower in the future. This trend might be reversed after 2050 following the more intensive use of forest (resulting in reestablished younger forests stands) in the second half of the century.

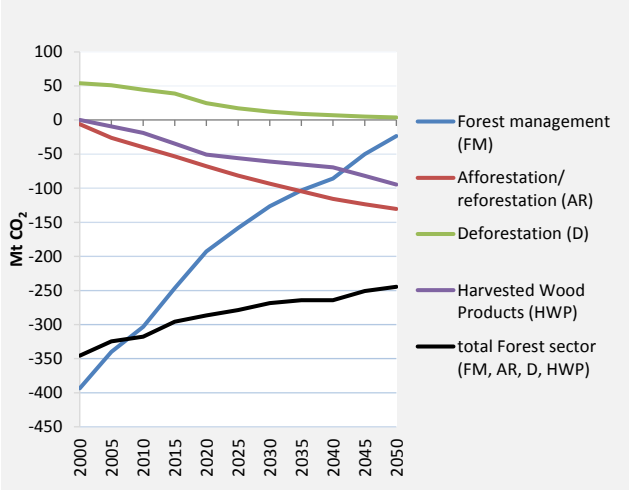
FIGURE 56: EU28 HARVEST REMOVALS AND INCREMENT IN 1.000 M3 UNTIL 2050



Simultaneously, the carbon sink in harvested wood products increases from-19 Mt CO_2 in 2010 to -61 Mt

CO_2 in 2030 and -95 Mt CO_2 in 2050 compensating the reduced sink in the managed forest to some degree. In addition, the carbon sink from afforested areas is also growing until 2050. Even though annual afforestation and reforestation rates decrease over time, 11 million ha (Mha) of land will be afforested until 2030, 16 Mha until 2050 (see Figure 55). In 2030, already 8% of the total forest area will be newly planted forests (10% in 2050). The total forest area is projected to increase from 140 Mha in 2010, to 146 Mha in 2030 and 150 Mha in 2050. In total, afforested areas are projected to sequester 94 Mt CO_2 in 2030 and 130 Mt CO_2 in 2050. With increasing age the new forests get more and more into a phase of high production and become gradually available for wood and biomass supply. Towards 2050 these forests are therefore also taking harvest pressure from older forests and thus help to keep the sink up in managed existing forests. Figure 57 shows the development of the carbon sink in the forest sector until 2050.

FIGURE 57: DEVELOPMENT OF THE EU28 CARBON SINK IN THE FOREST SECTOR UNTIL 2050



Emissions from deforestation continue to decrease from 45 Mt CO_2 in 2010, to 12 Mt CO_2 in 2030 and 4 Mt CO_2 in 2050 as deforestation drops from 74.000 ha in 2010 to 7.000 ha in 2050. This development is consistent with historic trends.

Emissions from cropland

Cropland is a net source of carbon dioxide emissions in EU28 at present. Over time, emissions are projected to decrease from 26 Mt CO_2 in 2010, to 14 Mt CO_2 in 2030 (44% decrease in comparison to 2010) and 16 Mt CO_2 in 2050 (38% decrease). The main driver for this decline is the projected establishment of short rotation tree plantations and lignocellulosic crops for renewable energy production which has a positive effect on the amount of carbon stored in the soil compared to conventional crops. Another important factor is the growing use of perennial crops such as miscanthus. The PRIMES biomass supply indicates that with growing demand the supply of these crops will grow because these are relatively cost-effective. In 2030, the area covered by perennial crops sums up to 7 Mha (7% of total cropland) and 9 Mha (9% of total cropland) in 2050. While carbon sequestration from perennials increases over time, emissions from conventional crops decrease as area declines. The conventional crop area is projected to decrease by 2 Mha until 2030 and 7 Mha until 2050.

Another important factor influencing soil carbon emissions from croplands is a saturation effect. Modeled soil carbon stocks converge towards equilibrium under a constant management regime. Disturbances of the equilibrium due to a change in management lead to a new equilibrium. The emissions or removals towards the equilibrium get smaller over time as the new management continues. This is especially true for more intense management changes such as the conversion of annual crops into perennial crop cultivation. Emissions from cropland remaining cropland decline from 16 Mt CO_2 in 2010 to -3 Mt CO_2 in 2030 and -5 Mt CO_2 in 2050. Emissions from land converted to cropland rise from 9 Mt CO_2 to 17 Mt CO_2 in 2030 and 21 Mt CO_2 in 2050 as land converted to cropland starts emitting carbon when being cultivated. As a result total cropland emissions are expected to decline over time (see Figure 54).

The total cropland area is projected to increase slightly from 101 Mha in 2010, to 105 Mha in 2030 and 102 Mha in 2050 related to the increase in perennial crop cultivation. Cropland remaining cropland declines from 96 Mha in 2010 to 95 Mha in 2030 and 87 Mha in 2050. Land converted to cropland increases from 5 Mha in 2010 to 10 and 15 Mha in 2030 and 2050 respectively.

Emissions from grassland

Grasslands are a net carbon source at present in the EU28. Over time, however, they turn from being a net source in 2010 with emissions of 4 Mt CO_2 to a net carbon sink of -5 Mt CO_2 in 2030 and -12 Mt CO_2 2050. This result is mainly driven by land converted to grassland as this land use change tends to sequester carbon after conversion. Even though total grassland area decreases marginally from 62 Mha to 61 Mha by 2050, land converted to grassland sequesters by 2030 14 Mt CO_2 and by 2050 21 Mt CO_2 and turns grasslands into a net carbon sink. Grassland remaining grassland declines from 60 Mha in 2010 to 56 Mha in 2030 and 53 Mha in 2050 due to afforestation and expansion of perennials. Land converted to grassland increases from 2 Mha in 2010 to 5 Mha in 2030 and 8 Mha in 2050 in order to compensate for the loss of grasslands and meet livestock feeding demand.

Emissions from other land

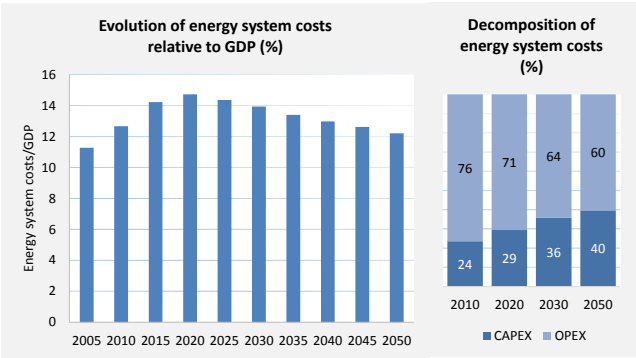
Emissions from other land, settlements and wetlands are not modeled explicitly in GLOBIOM and kept constant at 2010 levels as reported by UNFCCC[39]. Emissions from wetlands amount to 5 Mt CO_2, for settlements they amount to 39 Mt CO_2 and for other land 1 Mt CO_2. In EU28, around 22 Mha is covered by wetlands, 27 Mha by settlements and 26 Mha by other land according to UNFCCC reported data.

Total energy system and other mitigation costs

The considerable changes in the EU energy system and projected international fuel price developments drive strongly increasing energy system costs until 2020. This is attributable to direct capital expenditure payments both on the demand side (e.g. building insulation, replacing equipment with more efficient appliances, etc. triggered by energy efficiency policies) and on the supply side (refurbishment and new investments in power generation and transmission, needed to replace the existing capital stock). Additionally, increasing capital expenditures in power generation driven by the RES 2020 target are also reflected. Last but not least, strongly increasing international fossil fuel prices cause a significant further upward effect on energy system costs, both through direct fuel expenditures and indirectly through the electricity prices. Overall, in 2020 total system costs constitute 15% of the GDP, rising from 13% in 2010[40].

Beyond 2020 and throughout the remaining projection period, energy costs continue to increase in absolute terms but at a slower rate, below GDP growth, as the system reaps benefits from the investments undertaken in the previous decade (notably via fuel savings). In this period, the share of energy system costs in GDP is gradually decreasing, reaching 2010 levels in 2050.

FIGURE 58: EVOLUTION OF ENERGY SYSTEM COSTS[41]



Reflecting increasing capital intensiveness of the energy system, the share of CAPEX (capital costs and direct efficiency investments) in total system costs increases over time, reaching 40% in 2050 from 24% in 2010 (excluding ETS auction payments). Auction payments are very small compared to total energy system costs; it should be noted that auction payments do not represent an actual economic cost, as the revenues are recycled into the economy.

Regarding OPEX, overtime electrification of the residential and the tertiary sectors result in electricity costs becoming the main OPEX component for these sectors, instead of other fuel costs. The opposite ef-

[39] http://unfccc.int

[40] Total system costs include total energy system costs, costs related to process-CO_2 abatement and non-CO_2 GHG abatement. The energy system costs have been calculated on the basis of nominal discount rates, despite the use of lower discount rates for simulating economic decision making under framework conditions that strongly foster energy efficiency (see part on modelling of energy efficiency policies). Further modelling work will look into an alternative cost reporting methodology.

[41] Excluding ETS auction payments, given that they result in corresponding auction revenues.

fect is observed for the industrial sector, owing to decreasing long term electricity prices.

Conclusion

The portfolio of policies and binding targets that have been adopted so far in the EU are expected to bring about considerable changes in the energy system relative to past trends. Key policies that have been examined in the Reference scenario are GHG reduction policies like the EU ETS along with efforts to reach targeted RES shares and improve significantly energy efficiency, including CO_2 standards for vehicles. The latter two policy lines strongly support GHG reduction, involving a large number of synergies and also some overlaps, e.g. regarding the downward effect of RES electricity penetration and electricity savings on ETS prices. This has been addressed in modelling the binding 2020 GHG targets as effect of the EU ETS, the RES targets and other policies. An additional non-ETS target-related policy driver to ensure achievement turned out not to be necessary.

At the same time, competitive energy provision for businesses as well as affordability of energy use are key issues for economic and social development in the EU. Therefore this scenario analysis has also focused on relevant indicators in this respect, showing overall developments and potential trade-offs. Energy security issues have also been addressed, thereby giving a comprehensive picture on the possible implications of pursuing the adopted policies under the macro-economic and world energy framework conditions that have been modelled on the basis of the long term economic and demographic analyses undertaken in collaboration with Member States experts (notably the EPC/DG ECFIN Ageing Report).

GHG reduction is progressing in all sectors, but decarbonisation is particularly strong in power generation given the large number of options for decarbonisation in this sector and despite the move towards using more electricity. This higher electricity use reflects its convenience at use as well as the synergies from replacing CO_2 emitting fossil fuels (where CCS is not feasible or not economic) with electricity, which in turn is generated in a low carbon mode. Indeed, the main characteristic of the future EU energy system is a significant reduction of the carbon intensity of power generation. Another key feature is the decoupling of energy consumption from GDP growth, which is more limited for electricity due to the increasing shares of electricity in final energy consumption. Overall, despite significant economic growth making the EU economy 78% larger in 2050 than it was in 2010, there is a decline of total energy consumption by 8%.

The period until 2020 involves the most sweeping transitions due to the legally binding targets of the 20-20-20 Energy and Climate Package, the provisions of the EED and the CO_2 regulations for LDVs. The projection indicates that the measures contained in the EED combined with mandatory objectives on renewables, the EU ETS and other EU and national efficiency and climate policies, coupled with the steep increase in fossil fuel prices, induce energy savings of the order of 17% in 2020 relative to the benchmark (Baseline 2007 scenario). RES targets would be achieved, indeed slightly overachieved. Regarding GHG emissions, target levels (for all sectors combined and for the non-ETS sectors) would be even surpassed at the EU level. This is due to the economic crisis and a combination of policies that lead at an EU aggregate level to lower non-ETS emissions than resulting from the aggregate binding Member State targets in the Effort Sharing Decision and rising ETS surplus allowances until after 2020. Consequently, in 2020 GHG emissions fall by 24% compared to 1990, further decreasing to 32% below the 1990 level in 2030 and by 44% in 2050. However, this significant decrease falls still considerably short of the EU's 2050 GHG objective. The transitions of the 2010-20 decade set the ground for future developments. Beyond 2020, no RES targets have been agreed and no additional efficiency policies are defined, although efficiency measures continue to bear improvements in energy consumption until 2030 and beyond (notably the long term effects of more energy efficient investment brought about by different measures including eco-design, CO_2 standards for LDVs, etc. Energy consumption in 2030 is 21% lower than the 2030 energy consumption of the benchmark case (Baseline 2007). Moreover, the continuation of the ETS, leading to large decrease of ETS allowances throughout the projection period, constitutes a significant driver of continuing RES penetration, energy efficiency and further emissions reduction. In 2030, GHG emissions are projected to be reduced by 32% relative to 1990.

The changes that the power generation sector undergoes entail considerable capital intensive investments, as well as investments in the transmission and distribution system. These have an upward effect on electricity prices and energy system costs in the transitional period until 2020, enhanced further by the increased fossil fuel prices. Beyond 2020, however, electricity prices stabilize and even decrease. A general effect on total energy system costs is that they become more capital intensive over time. After having undergone all the structural adjustments to cope with the 2020 targets and policies, total energy system costs grow slower than GDP, leading to decreasing ratio of energy system costs to GDP in the period 2020-50.

Finally, the intense deployment of RES following notably the investment to achieve the 2020 targets results in sizeable decrease in external energy dependence. In the long run, however, the limited availability of indigenous fossil fuel resources (due to depletion of domestic resources) as well as limited additional biomass imports lead to total net energy imports increasing again (after 2035) This mainly concerns natural gas, which according to the projection will play a crucial role in the context of emission reduction targets and as back-up for variable RES.

GLOSSARY

Aviation: Aviation activity includes only intra-EU (domestic and EU international) air transportation. Energy consumption and CO_2 emissions in aviation reflects sales of fuels at the point of refuelling, irrespective of airplane destination. They approximately correspond to all outgoing domestic and international flights.

Biofuels: Biofuels include ethanol, biodiesel, bio-kerosene and bio heavy.

Carbon capture and storage (CCS): Carbon capture and geological storage is a technique for trapping carbon dioxide emitted from large point sources, compressing it, and transporting it to a suitable storage site where it is injected into the ground.

Carbon intensity: The amount of CO_2 emitted per unit of energy consumed or produced (t of CO_2/tonne of oil equivalent (toe) or MWh).

CO_2 Emissions to GDP: The amount of CO_2 emitted per unit of GDP (carbon intensity of GDP - t of CO_2/M Euro).

Cogeneration thermal plant: A system using a common energy source to produce both electricity and steam for other uses, resulting in increased fuel efficiency (see also: CHP).

Combined Cycle Gas Turbine plant (CCGT): A technology which combines gas turbines and steam turbines, connected to one or more electrical generators at the same plant. The gas turbine (usually fuelled by natural gas or oil) produces mechanical power, which drives the generator, and heat in the form of hot exhaust gases. These gases are fed to a boiler, where steam is raised at pressure to drive a conventional steam turbine, which is also connected to an electrical generator. This has the effect of producing additional electricity from the same fuel compared to an open cycle turbine.

Combined Heat and Power (CHP): This means cogeneration of useful heat and power (electricity) in a single process. In contrast to conventional power plants that convert only a limited part of the primary energy into electricity with the remainder of this energy being discharged as waste heat, CHP makes use of a greater proportion of this energy for e.g. industrial processes, district heating, and space heating. CHP therefore improves energy efficiency (see also: cogeneration thermal plant).

Efficiency for thermal electricity production: A measure of the efficiency of fuel conversion into electricity and useful heat. It is calculated as heat and electricity output divided by the calorific value of input fuel.

Efficiency indicator in freight transport (activity related): Energy efficiency in freight transport is calculated on the basis of energy use per tonne-km. Given the existence of some methodological inconsistencies between transport and energy statistics, absolute numbers (especially at the level of individual Member States) might be misleading in some cases. For that reason, the numbers given are only illustrative of the trends in certain cases.

Efficiency indicator in passenger transport (activity related): Energy efficiency in passenger transport is calculated on the basis of energy use per passenger-km travelled. Issues related to consistency of transport and energy statistics also apply to passenger transport (see also: Efficiency indicator in freight transport).

Energy branch consumption: Energy consumed in refineries, electricity and steam generation and in other transformation processes.

Energy intensity: energy consumption/GDP or another indicator for economic activity.

Energy intensive industries: Iron and steel, non-ferrous metals, chemicals, non-metallic minerals, and paper and pulp industries.

Energy Service Company (ESCO): A company that implements a broad range of energy efficiency projects.

EU Emissions Trading System (EU-ETS): A scheme for greenhouse gas emissions allowance trading within the Community, established by Directive 2003/87/EC in order to promote reductions in greenhouse gas emissions in a cost-effective and economically efficient manner. Installations included in the scheme are combustion plants, oil refineries, coke ovens, iron and steel plants, and factories producing cement, glass, lime, brick, ceramics, pulp and paper. Recent amendments (2008/101/EC and 2009/29/EC) have enlarged its scope to include aviation and further process emissions.

Feed-in tariff: The price per unit (of electricity) that an eligible renewable electricity generator receives according to cost-based calculations for the specific resource used.

Final energy demand: Energy consumed in the transport, industrial, household, services and agriculture sectors; the latter two sectors are sometimes aggregated and named "tertiary". It excludes deliveries to the energy transformation sector (e.g. power plants) and to the energy branch. It includes electricity consumption in the above mentioned final demand sectors.

Freight transport activity: Covers goods transport by road, rail and inland navigation. Road transport activity is defined according to the nationality principle, in line with the available statistics from EUROSTAT.

Fuel cells: A fuel cell is an electrochemical energy conversion device converting hydrogen and oxygen into electricity and heat with the help of catalysts. The fuel cell provides a direct current voltage that can be used to power various electrical devices including motors.

Fuel input to power generation: Fuel use in power plants and CHP plants.

Gas: Includes natural gas, blast furnace gas, coke-oven gas and gasworks gas.

Generation capacity: The maximum rated output of a generator, prime mover, or other electric power production equipment under specific conditions designated by the manufacturer.

Geothermal plant: A plant in which the prime mover is a steam turbine, which is driven either by steam produced from naturally hot water or by natural steam that derives its energy from heat in rocks or fluids beneath the surface of the earth. The energy is extracted by drilling and/or pumping.

GINI coefficient: (or index) Measures distribution inequalities present in statistics, such as income distribution variation among EU Member States. A Gini coefficient of zero expresses an exactly equal income between MS.

Gross Inland Consumption (or primary energy consumption): Quantity of energy consumed within the borders of a country. It is calculated as primary production + recovered products + imports +/- stock changes – exports – bunkers (i.e. quantities supplied to international sea-shipping).

Gross Inland Consumption/GDP: Energy intensity indicator calculated as the ratio of total energy consumption to GDP – (toe/M Euro).

Hydro power plant: A plant that produces energy through the use of moving water. In this report, hydro excludes pumped storage plants that generate electricity during peak load periods by using water previously pumped into an elevated storage reservoir during off-peak periods when excess generating capacity is available. Energy losses in pumping are accounted for separately.

Inland navigation: Covers inland waterways and national maritime transport, for the purpose of ensuring consistency with the energy balances. International maritime is not included in the above category as, according to EUROSTAT energy balances, energy needs for international shipping are allocated to bunkers.

Import dependency: Demonstrates the extent to which a country relies upon imports in order to meet its energy needs.

Non-fossil fuels: Nuclear and renewable energy sources.

Non-energy uses: The use of petrochemicals and other energy carriers for purposes other than energy production, such as chemical feed-stocks, lubricants and asphalt for road construction.

Nuclear power plant: A plant in which a nuclear fission chain reaction can be initiated, controlled, and sustained at a specific rate for production of energy.

Oil: Includes crude oil, feed-stocks, refinery gas, liquefied petroleum gas, kerosene, gasoline, diesel oil, fuel oil, naphtha and other petroleum products.

Peak devices: Gas turbines, internal combustion engines and other small-scale thermal power plants which are usually used to supply electricity in peak hours.

Passenger transport activity: Passenger transport activity covers road transport (buses and coaches, passenger cars and vans, powered 2-wheelers), rail transport, aviation and inland navigation. Tram and metro activity is provided together with rail in the reporting by MS.

Primary production: Total indigenous production. In PRIMES result sheets (Appendix 2) it also includes recovered products.

Renewable energy sources: Energy resources which are naturally replenishing but flow-limited. These are virtually inexhaustible but limited in the amount of energy that is available per unit of time. Renewable energy resources include: biomass, waste energy, hydro, wind, geothermal, solar, wave and tidal energy.

Solar power plant: A plant producing energy with the use of radiant energy from the sun; includes solar thermal and photovoltaic (direct conversion of solar energy into electricity) plants.

Solids: Include both primary products (hard coal and lignite) and derived fuels (patent fuels, coke, tar, pitch and benzole).

Thermal power plants: Type of electricity generating plant in which the source of energy for the prime mover is heat (nuclear power plants are excluded).

Wind power plant: Typically, a group of wind turbines supplying electricity directly to a consumer, or interconnected to a common transmission or distribution system. Offshore wind includes windmills located at sea (coastal wind mills are usually included in onshore wind).

Source: PRIMES

(A) including the part of electricity and heat generated by renewables

(B) excluding payments for auctioned emission allowances (if applicable)

(C) including pipeline transport and other non-specified transport

(D) according to Eurostat's indicator "Share of Renewables in Gross Final Energy Consumption", calculated as ratio of renewable energy in all sectors including the part of electricity and heat generated by renewables over final energy demand increased by distribution losses and self consumption of electricity and steam plants

(E) for years 2000 to 2010, total gross electricity generation by source as reported in this table and total gross electricity generation reported in table (A), as part of the energy balance, slightly differ becauses of differences in the respective statistical sources

(F) electricity generated over maximum potential generation based on net power capacity

(G) energy demand in transport reported in table (B) does not include pipeline transport and other non-specified transport compared to table (A) where this category is included

Disclaimer: Energy and transport statistics reported in this publication and used for the modelling are taken mainly from Eurostat and from the publications "EU Energy in Figures" of the Directorate General for Energy and "EU Transport in Figures" of the Directorate General for Mobility and Transport. Energy and transport statistical concepts have developed differently in the past according to their individual purposes. Energy demand in transport reflects usually sales of fuels at the point of refuelling, which may differ from the region of consumption. This is particularly relevant for air transport and road freight transport. For road freight, transport activity is defined according to the nationality principle because of the lack of sufficiently long time series defined according to the territoriality principle. These differences should be borne in mind when comparing energy and transport figures. This applies in particular to transport activity ratios, such as energy efficiency in freight transport, which is measured in tonnes of oil equivalent per million tonne-km.

Abbreviations

GIC: Gross Inland Consumption
CHP: combined heat and power

Units

toe: tonne of oil equivalent, or 10^{7} kilocalories, or 41.86 GJ (Gigajoule)
ktoe: 1000 toe
MW: Megawatt or 10^{6} watt
MWh: megawatt-hour or 10^{6} watt-hours
GWh: gigawatt-hour or 10^{9} watt-hours
t: metric tonnes, or 1000 kilogrammes
Mt: Million metric tonnes
km: kilometre
pkm: passenger-kilometre (one passenger transported a distance of one kilometre)
tkm: tonne-kilometre (one tonne transported a distance of one kilometre)
Gpkm: Giga passenger-kilometre, or 10^{9} passenger-kilometre
Gtkm: Giga tonne-kilometre, or 10^{9} tonne-kilometre

HOW TO OBTAIN EU PUBLICATIONS

Free publications:

- via EU Bookshop (http://bookshop.europa.eu);
- at the European Union's representations or delegations. You can obtain their contact details on the Internet (http://ec.europa.eu) or by sending a fax to +352 2929-42758.

Priced publications:

- via EU Bookshop (http://bookshop.europa.eu).

Priced subscriptions (e.g. annual series of the *Official Journal of the European Union* and reports of cases before the Court of Justice of the European Union):

- via one of the sales agents of the Publications Office of the European Union (http://publications.europa.eu/others/agents/index_en.htm).
